CLINICAL MEDICINE,

*Given at the London Hospital*By SIR ANDREW CLARK, BART, MD
LLD CAMB, LL D ABERD, FRS,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

(Reported for THE LANCET and revised by the Author)

[WITH COLOURED PLATE.]

III²DEMONSTRATION OF CASES OF FIBROID LUNG DISEASE,
WITH REMARKS

FORMS OF FIBROID DISEASE.

GENTLEMEN,—By the kindness of Drs Hadley and Chaplin you have had the opportunity of seeing several cases of fibroid disease of the lung, and here to-day we are going to assemble a number of other cases that you may learn the different forms which these fibroid affections of the lung assume. Now there are three different degrees of fibroid disease which it is worth your while to remember. First, there is the simple fibroid lung, secondly, there is the fibroid lung with dilatations, and thirdly, the fibroid lung with or without dilatations, but with cavities. To the first we give the name of fibroid lung, to the second the name of bronchiectasis (but I shall consider that with you on another occasion), and to the last the term "fibroid phthisis" has been applied.

FIBROID PHTHISIS

In reference to fibroid phthisis it is very important to remember the definition we have given of pulmonary phthisis—that is to say, it is "that assemblage and progression of symptoms associated with and dependent upon the ulcerative or suppurative destruction of more or less circumscribed non malignant deposits in the lung." This is our generic phthisis varieties are indicated by the prefix of adjectives indicating the physical nature of the consolidation, and hence it is that any fibroid induration of the lung with cavities therein has been called fibroid phthisis. The next point, and it is only the salient points that I wish to reproduce before you to-day is the essential characteristics of this fibroid disease of the lung. The first is that it is as a rule non febrile except on occasions when intercurrent disease arises, the second is that it is chronic, the third is that it is compatible with prolonged average good health, and the last that I think worth while to mention to you upon this occasion is the fact that it is not incompatible with the longest duration of human life. A few years ago some of you remember—Dr Hadley remembers—there was a patient in the female ward seventy-six years of age with fibroid phthisis of the left lung.

COMPLICATIONS IN FIBROID AFFECTIONS OF THE LUNG

The next point of importance is the question of the complications to which this fibroid affection of the lung is subject. There is first of all gastro hepatic catarrh, secondly, albuminuria, thirdly, attacks of diarrhoea, fourthly, hæmoptysis, fifthly, dropsy; and lastly, nephritis. Now I here interpolate an important observation, it is, that I have never yet seen a case of this affection of ten years standing without albuminuria, and that albumen frequently appears in the urine even before the second year of the disease. The last point to which I shall now advert in relation to this subject is the nosological position of fibroid disease. With respect to the first stage of it, mere fibroid consolidation or induration, there is no conflict of opinion. Concerning the second stage, that is with fibroid induration and dilatation, more or less, of the bronchial tubes, there is considerable discussion. A tendency has shown itself among certain observers to call this form bronchiectasis, but to call it by this term is merely to take note of one of the leading pathological factors of fibroid disease and to make it the distinguishing characteristic. I

do not think there is anything intrinsically wrong in this, but it diverts the mind from the real cause of the bronchial dilatation which is the fibroid affection of the lung, and this affection is either primary or secondary, rarely primary but usually secondary to a dry pleurisy, to prolonged bronchitis, and to unreduced pneumonic deposits. The third term, "fibroid phthisis," is maintained on account of the definition which was given to you at the beginning of this instruction. But there are two nosological aspects of it, and here again there is the greatest conflict of opinion.

TUBERCULO FIBROID PHTHISIS

I wish to explain that in all these cases which you have seen of this disease, and they have been many, no tubercular bacilli have been found, and hence, in no sense of the word, according to the present state of pathological knowledge, can these be called cases of true tubercular disease, because, as you know, at present the criterion of a tubercular affection is the presence of the tubercular bacilli in the affected part. Now in this fibroid induration one of the most interesting points is that in the greatest number of cases no tubercular bacilli make their appearance at any time. But in a certain small proportion of cases, when the lung has been attacked by colds or pleurisies or pneumonia, tubercular bacilli make their appearance, cavities form, and then in harmony with prevailing doctrines, the term tuberculo-fibroid phthisis may be justly employed. And of course, if a case came before us here of fibroid disease of the lung, with or without dilated bronchi, with cavities and with bacilli in the expectoration, we should be bound, in just loyalty to the present state of our knowledge, to call that case tubercular phthisis. But we are bound also to recognise the fact of the presence of the fibroid material which makes all the difference between what one may call ordinary tubercular phthisis where there is no such large amount of fibroid disease and that kind of tubercular phthisis where there is. The difference appears in this way that whenever in a case of tubercular phthisis the lung is riddled with small cavities and studded with tubercles surrounded by pneumonic exudations the progress of that disease is as a rule febrile and comparatively rapid, but, on the other hand, mark this that whether bacilli be present or not the course of that case of tubercular phthisis in which the fibroid element dominates the rest of the pathological changes will be very slow, it will be unattended with fever, and it may last for many years.

ACCOMPANIMENTS OF TUBERCLE.

I wish here to emphasise the fact that two marked secondary structural affections either accompany or follow the deposit of tubercle in the lung. One of these is the occurrence of a pneumonic exudation round the tubercles and the other is the appearance of a zone of fibroid tissue, and you can with perfect confidence foretell the general course of tubercular phthisis by the dominance of one or other of these secondary affections. If fibroid tissue for the main part surrounds the tubercles the progress of the case will be slow and fever will not be prominent, but if, on the other hand, pneumonic changes dominate the progress of the case will be rapid and fever will prevail.

RESUME.

That is all I have to say just now, but I will bring in the cases and I will put them before you, and I hope that what you will see to-day will satisfy you that this fibroid disease of the lung is not very rare, and that it is very important for the safety of the patient and your own credit that you should know the causal history of it—namely, its slowness its freedom from fever and the duration of time over which it may extend.

GENERAL HISTORY OF THE CASE.

I purpose now considering with you the case of a little girl provided for our instruction by Drs Hadley and Chaplin. You see she is undergrown and somewhat ill developed but she is well nourished and there is no history of loss of flesh. She has a large head, the features are swollen, the eyelids are baggy, the face is purplish, she is round shouldered and has clubbed finger ends. Menstruation has not yet appeared. There is no family history of phthisis, of alcoholism or of syphilis. The patient has been ill since she was two years and a half old and the illness began with a severe whooping-cough followed a few months afterwards by measles. Since then she has never been free from chest trouble, becoming worse in winter and better in summer. At present she suffers from cough from rather profuse expectoration and from shortness of breath. But for these

likely to avert complications or conduct them, if they arise, to a successful issue and to prolong life? I do not intend to discuss to-day the treatment of this patient, but some days hence, when I have examined with you a few more cases of fibroid disease of the lung and have made you familiar with their different aspects, I shall discuss the question of treatment on such broad lines as will convey to your minds those general principles of management which my experience has taught me to adopt and employ

[The coloured plate presented with this lecture represents a section of lung with diffuse fibroid change, accompanied by thickened and dilated bronchi. The whole lung is much contracted and all but the very base is involved in the change, which is especially marked in the inter lobular septa and around the vessels and bronchi, the spongy texture being in great measure replaced by fibrous tissue. Some enlarged, indurated and pigmented glands are to be seen at the root of the lung—ED L.]

THE CORRELATION OF STRUCTURE, ACTION AND THOUGHT, INAUGURAL ADDRESS,

*Delivered at the Royal Medical Society of Edinburgh on
October 21st, 1892,*

BY THOMAS LAUDER BRUNTON, M.D.,
D.Sc. EDIN., LL.D. (HON.) ABERD., F.R.C.P., F.R.S.,
ASSISTANT PHYSICIAN AND LECTURER ON MATERIA MEDICA AND
THERAPEUTICS IN ST BARTHOLOMEW'S HOSPITAL ETC.

[WITH COLOURED PLATE.]

MR. PRESIDENT AND GENTLEMEN,—Allow me to return you my most grateful thanks for the honour which you have done me in asking me to address you to night. I believe that there are none here excepting myself who can understand how grateful I feel, because no one else can know how much I owe to this Society. I have been compelled during my life to do a good deal of speaking and of writing and yet these are the two things which above all others I dislike and for which I am naturally entirely unfit. Had it not been for the training which I received in this Society I do not think that I should ever have been able to speak in public at all. In relation to speaking and writing I often recall an anecdote told me by my poor friend the late Dr Milner Fothergill

But it is not only in speaking and writing that I owe my training to the Royal Medical Society of Edinburgh, I owe to it also my first initiation into scientific methods—my first instruction in scientific scepticism. I well remember that on one occasion a member made a certain statement, he had no sooner sat down than he was challenged by my friend, Dr John Wylie. The first member again rose to his feet and maintained that his statement was true, and that his facts were correct because Professor So-and-so had said so. Again Dr Wylie rose, and with the simple question, "But is Professor So-and-so right?" swept away the ground from under his opponent's feet and gave me a new insight into scientific evidence. Previously I had been inclined to accept all the dicta of the professors as Gospel truth, but from that time onwards I accepted them only with the proviso that Professor So-and-so might possibly be wrong. Training like this, gained by a student in the discussions at the meetings here, is of the utmost possible importance as supplying a valuable part of medical education and complementing the instruction which he gains in the lecture rooms, it enables him to sift the statements which he there hears and to assimilate them in his own mind, so that they become as it were part of himself, and afford him a basis of knowledge upon which he not only can act in daily life, but from which he may advance onwards and benefit both his profession and the world at large by new discoveries. This training is so invaluable that I should look upon anything which would interfere with it as detrimental to the student, for a little knowledge, like a little food, if well assimilated, is more useful than an undigested mass, which may be not only useless but positively injurious.

The numerous discoveries which have been made during the twenty nine years which have elapsed since I first took my seat in this hall as a member of the Society have tended to increase the mass of facts which the student has to learn, and the numerous examinations have tended to foster a system of cramming which is totally distinct from that of true education. For the purpose of examination the student is tempted to load his memory with many details and to learn by heart statements which may or may not be true, simply for the purpose of committing them to paper and thus gaining good marks in competitive examinations without considering in the least whether these statements are true, or whether the facts, so called, are likely to help him at all in his future life. The period during which I regularly attended the meetings of this Society was a transitional one, because the number of examinations, competitive and professional, was then beginning to increase. I trust it is not true, but I have heard that since my time the examination incubus has been weighing even more heavily upon men than it did then, and has been interfering to some extent with the activity of the discussions in this society. Yet even if it were true it can hardly be wondered

(After Haeckel.)

regarding a beaver which an American said he had chased so hard that it had been forced to climb up a tree to escape him. "But," said his hearer, "beavers cannot climb trees." "Well," replied the American, "I guess this one had just got to." Now this Society played to me the part that the American did to the beaver and forced me both to speak and write, and I am therefore very grateful to it. My first attempt at writing was the dissertation which the rules of the Society demanded and my first attempt at speaking was made in this room when I stammered out half a dozen words, each one broken into bits by the palpitations of my heart, and then thankfully sat down.

at, for it seems to me that we are living at a period which is not only one of the utmost activity, one of the most startling progress, and one of the keenest excitement for all engaged in research, but at the same time it is one of the utmost difficulty for all those who are engaged in the study of medicine, surgery and the allied sciences. For the number of facts is not only enormously great, but is daily increasing at a rate which threatens to make it almost impossible for any ordinary memory to retain them all. Yet the darkest hour is that before the dawn and I believe that shortly medical study will become very much easier. The great difficulty that the student has in remembering facts is that

symptoms and her undue liability to feverish colds, the patient declares that she would be quite well. The cough is paroxysmal and often ends in retching or vomiting. The expectoration is muco purulent, abundant, and often discharged in mouthfuls at the close of a paroxysm of coughing. It is not fetid, and, although many times microscopically examined by various persons, no tubercular bacilli have been found in it.

EXAMINATION OF THE CHEST

On examining the chest we find that the thorax is barrel shaped, that its movements are unequal, and that it rises rather than expands on inspiration. The right side is much smaller than the left, it is flattened and retracted, it moves very little during respiration and the intercostal spaces are almost effaced, the veins of the neck are distended and are not emptied on inspiration. Portions of the upper and lower divisions of this side are drawn inwards during the inspiratory movements, the cervical and upper brachial regions are a little swollen, and the respiratory movements, which are laboured, are about 25 in the minute. On more narrowly examining this right side you can see the impulse of the heart immediately in front of the right nipple, whereas no cardiac impulse can be seen or felt in its usual position.

THE POSITION OF THE HEART

Let me here arrest your attention for a moment to consider this instructive sign of disease which I have just mentioned to you. It is of the first importance to determine early in the examination of a chest the place where the heart is beating. This determination will preserve you from many mistakes, and sometimes it will throw a great light on the nature of the disease which you are investigating. When you find the heart beating in the right side of the thorax the displacement is due to an error of development, to air or to fluid in the left pleura which has pushed the heart aside, or to a contraction of the right lung which has pulled it over to fill the space created by the contracted organ. In the case before us we shall soon see that as there is no error of development and no air or fluid in the left pleura the displacement of the heart which exists must be due to a contracted lung.

UNUSUAL ACTION OF THE HEART

As I have spoken of displacement of the heart let me add a word or two about its action. The heart, which is somewhat enlarged, acts in a very notable way. Its action is clear, strong, deliberate, the first and second sounds are loud and sharply defined, and the second sound follows the first at a considerably longer interval of time than occurs in the normal condition. These characteristics of the heart's action in this case are very different from the characteristics of the heart's action in ordinary tubercular phthisis, and so common are they in cases of fibroid lung that I have been able, many times to discover the state of the lung merely from the mode of action of the heart. I shall probably have to recur to this subject on another occasion.

THE CONDITION OF THE RIGHT LUNG

Let us now return to the condition of the right lung. I have already pointed out to you that the right side of the thorax is retracted and moves imperfectly in the upper third except over the divisions of the larger bronchi. Tactile vocal fremitus is diminished and in the lower two thirds it is almost annulled. There is dullness to percussion over the whole of the right side posteriorly, moderate above and complete from about the middle to the base of the lung. In front the dullness has a tubular character somewhat resembling the note elicited on percussing the summit of a child's lung the lower part of which is surrounded and compressed by fluid.

AUSCULTATION

Over the summit of the lung one hears bronchial breathing coarse, moist, subcrepant rales and pleural creaking. The vocal resonance is bronchophonic. From the clavicle to the nipple you can hear coarse moist crepitations and creaking. From the nipple downwards scarcely any sounds are heard and vocal resonance is almost inaudible. Below the spine of the scapula and towards its inner side the tactile vocal fremitus is much increased and there is bronchial breathing. The vesicular murmur is replaced by loud subcrepant rales, the vocal resonance is bronchophonic and almost pectoriloquous, and pleural creakings are heard throughout both respiratory movements. Immediately below this only faint moist crepitations are heard with diminished vocal resonance. Throughout the base the respiratory sounds and resonances are inaudible.

CONCURRENT PHYSICAL SIGNS AND THEIR INTERPRETATION

Let us here pause for a moment to consider this concurrence of physical signs present in the base of the lung, partial effacement of the intercostal spaces, an almost even surface, diminished movement, abolition of tactile vocal fremitus, inaudible breath sounds and suppressed vocal resonance. What interpretation would ordinarily be placed upon this assemblage of physical signs? Without the closest critical examination what interpretation is indeed often put upon them? Often such a concurrence of physical signs is held to be conclusive as to the presence of fluid in the pleural cavity, and often operations, not always without peril, are performed for its withdrawal. Doubtless exploratory operations are in some circumstances unavoidable, and usually they are harmless, but, on the other hand, it is desirable to avoid the performance of an operation which is unnecessary and may be injurious. A careful study of the physical signs will generally prevent you from forming an erroneous judgment. If there are diminished movement and contraction of the affected part, if such dullness as may be present is not influenced by the position of the patient, if the outlines of the dullness are the same in all postures, if any displacement of organs exists, if the displacement is towards the dullness and not from it, if pleural creaking is heard in the dull region and if the results of percussion and of auscultation vary somewhat at different points you may be almost certain without further knowledge of the case that you are dealing with a consolidated lung. But you cannot be quite certain, for on rare occasions small empyemata or locular pleuritic effusions exist, and no refinements of physical exploration and no degree of skill in their use will enable you conclusively to distinguish between them. You must explore, and in exploring you must remember that in a few cases death has resulted from this simple operation.

GENERAL CONDITION OF THE PATIENT—DIAGNOSIS

Resuming our examination of the patient we find that there is no conclusive evidence of the existence of disease in the left lung. As I have already stated the cough is paroxysmal, and in the morning it sometimes brings about retching with the discharge of muco purulent sputa devoid of fœtor. In the sputa no tubercular bacilli have been found and no connected areolæ of elastic tissue, on the other hand, every specimen examined has been found swarming with micro-organisms of various kinds. Now, let us turn to the general condition of the patient in order to determine if it has been in any way affected by the presence and persistence of the disease of the right lung. The tongue is large, white, watery, indented, it is a catarrhal tongue. The appetite is good, there is no indigestion, the bowels are regular, the urine is abundant and doubtfully albuminous. There is no evidence of disease or of material disorder of the nervous system. To repeat what I said of the patient at the beginning she feels quite well except for the discomforts caused by the varying conditions of her affected lung, and those discomforts, as you have seen, are neither constant nor serious. What is the nature of the patient's malady? The reply will vary according to the school of thought from which the reply may emanate. For example, in one case the malady will be called "contractile phthisis," in a second it will be called "tuberculosis with contraction" and in a third it will be called "bronchiectasis." For my own part in obedience to what I believe to be a simpler and more scientific terminology, I diagnose the disease as a fibroid lung with dilatation of bronchial tubes and perhaps a small cavity. It should be, I think, a cardinal principle in naming that the name applied should involve no hypothesis which, although accepted to-day may be rejected to-morrow, and that if possible the designation of any given disease should be founded on some physical and abiding quality of its nature. It is mainly to improper naming that we owe the confusion of ideas which at this time invest and enter into all our discussions concerning tuberculosis and pulmonary phthisis.

THE PROGNOSIS

What now is to be said of the future of this case? Liable to many complications which may imperil and terminate life—to bronchitis, pneumonia, pleurisy, hæmoptysis, to nephritis and to general dropsy—the patient may nevertheless, with judicious care in the management of her daily health, achieve the longest duration of human life. What is the treatment to be pursued in this case? By what system of management, by what administration of drugs are we most

cramped for room, and periodically burst its shell, leaving itself naked, weak and defenceless. The right thing to do is evidently to do like the vertebræ, and have the hard parts inside, and the soft parts outside, but the relationship of these parts is a sore task upon the student's memory, and to many a one anatomy is a burden too heavy to be borne and the unfortunate youth is forced by it to leave the study of medicine and turn his attention to some easier pursuit.

Now, I think that with a little trouble one may find a way of linking anatomical relationships together in a more rational way than that of "Bodfi," a word which in my student days was used as a mnemonic to describe the form of the hippo campal convolution of the brain—backwards, outwards, downwards, forwards and inwards. The word also served to describe the course of the ribs, but Dr Anderson Stewart has shown us how naturally the peculiar twist the ribs take in a man arises from his upright position. Taking a circular steel hoop, and simply hanging it up by one side, he shows that it

FIG 6

Diagram of shoulder joint, to show the capsule.

FIG 7

Diagram of ligaments of phalanges—a capsule and lateral ligaments.

assumes an oval shape, like that of the thorax of animals going upon four legs and whose ribs hang vertically from the spine. On raising this up by one point it becomes twisted upon itself and takes precisely the peculiar bend which the ribs possess in man. The advantage of a naturally jointed skeleton is so obvious that I need not further discuss it here, nor need I discuss the texture of bone which has been so admirably treated of by my friend Dr Donald MacAlister of Cambridge (Fig 5).

The ligaments and the joints were to me most puzzling until Dr Joseph Bell pointed out to me how very simple they were. What is wanted in a joint is a capsule to go round it so as to hold the ends of the bones together and prevent the synovial fluid from oozing out. If the bones have to move freely in all directions they must have a ball and socket joint, as at the shoulder (Fig 6) and at the hip, and there you will

FIG 8

Diagram of the ligaments of carpus as seen from behind. Besides these there are ligaments passing in various directions so as to bind the bones more firmly to each other.

have a simple capsule because it cannot be particularly strengthened at one point or another without interfering with freedom of movement. In the case of a hinge-joint, such as those of the fingers or toes, elbows or knees, you will have the capsule remaining thin at the front and back so as to leave the movement free, but you will have it strengthened at the sides so as to tie (Fig 7) the bones more firmly together, and the stronger parts are called lateral ligaments. If several bones have to be connected each one must be tied first of all to the one nearest it, and then two or three must be tied together at a time, and in this way we get the network of ligaments which we find at the wrist and tarsus (Fig 8). The same thing is true

of muscles and, as Professor Goodair used to point out the muscles of the back, so perplexing at first, are really quite simple in their arrangement. For each of the spinæ vertebrae has to be bent and straightened and has also to rotate more or less upon its neighbours, so as to allow the upper part of the body to swing round upon the lower. We have therefore muscles going from the spine of one vertebra to the spine of the next, and then muscular strips stretching over a few and then over many vertebrae, so as to straighten the spine either in part or whole, as the movements may require. A similar arrangement holds good for the muscles passing from the spines to the lateral processes and which rotate the vertebrae on one another.

But if we are to group the muscles and nerves of the body into one easily remembered whole, we must see what is the chief function to be subserved by them, what is the centre of the little universe which they compose. The function of most imperious necessity is respiration. A man may starve himself to death, but he cannot kill himself by holding his breath. He may refuse food, but he cannot refuse air. In the child the function of respiration is the first which evidences itself after birth, and the muscles which subserve it are more fully developed and more perfectly innervated than others. The nerve channels which supply them are, as it might be termed, more deeply grooved than others and it is along these channels that superabundant energy overflows in the movements of laughter which evidence joy. This has been very fully and wisely explained by Herbert Spencer in his essay on "Laughter." But the great poet, whose recent death the whole civilised world is now deploring, has classed together in a few pregnant words the channels through which the overflow of energy may run in their proper order. In describing the joy evinced by a baby on seeing its mother, Tennyson says it

'began
A blind and babbling laughter, and to dance
Its body, and reach its falling innocent arms
And lazy lingering fingers."

The very parts which attain to the highest development in adult age and are capable of the finest and most dextrous movements, are the last to develop, and in infancy they are well described as "lazy lingering fingers." They take no part in the function of respiration, but they are of the utmost utility in the function which comes next to respiration in importance—namely, that of nutrition. The animal has to be fed, and all the arrangements of the limbs are more or less subservient to this primary object. In a fish the muscular masses at both sides of the spine bend the posterior part of the body and the tail alternately to one side or another, and so the animal is propelled through the water in search of food. No doubt these same muscles help it to escape danger, but their primary object is to obtain food, and if there be great hunger all animals will strive to feed, whatever be the risk they run in doing so. The movements of fish are simple compared with those of animals with limbs, and especially with those of man. Yet the arrangements of man's body are equally adapted with those of the fish for obtaining food.

There are two prevalent ideas regarding the origin of man. One is that he started full grown and perfectly developed from the dust of the ground, and lived in a garden which he "dressed and kept." The other is the Darwinian one, that man is developed from an arboreal animal like the monkey, though lower than the monkey. It matters not which of these ideas we take, because they perfectly agree that primitive man lived at first in a kind of paradise where he was not exposed to the attacks of wild beasts, and where he fed on the fruit which he plucked from the trees around him. The story of Adam and Eve has got the advantage of not only being more poetical, but it is very much more easy to discuss the actors in the scene by the names of Adam and Eve, than by the terms "male" and "female frugivorous animal."

Let us take then the story from Genesis. One day Eve went into the Garden of Eden—saw an apple upon a tree—plucked it, ate it, and then went to get another for Adam. In trying to analyse the muscles concerned in these acts, the easiest way is to go to your bedroom, strip off your clothes imitate Eve's action, and as you do so, feel out the individual muscles as they contract under the skin. This plan of learning the muscles is one which I used to follow as a student of anatomy, and I found it a very useful one indeed. If you do this you will find the muscles of the neck, shoulder, arm, fore arm and hand contracting successively or together in coördinated movements, which are beautifully adapted to

they are isolated and not coördinated together. In a book on memory which I once read the writer summed up his whole science in one sentence, "Observe, reflect, link thought with thought, and think of the impressions." This is easy to say but not so easy to do, and it is the difficulty of linking thought with thought that makes the tax upon the memory of the medical student so exceedingly great.

Now it seems to me that one of the objects which this Society should set before itself should be not only that of training its members in the art of speaking and writing, of sifting facts and criticising statements, but of linking together and coördinating the data which they are called upon to recollect. When the science of astronomy was younger and the earth was supposed to be the centre of the Universe, the motions of the planets were known with sufficient certainty to calculate eclipses, but they could only be brought into conformity with their supposed relationship to the earth as the centre by the most cumbrous system of

greatly to understand why the shape of the ovary, the nature of the ovule and the position of the embryo should be such important characters in determining the genus of plants, and I devoutly wished that plants had been made in such a way that one could settle their nature by characters visible to the naked eye and not requiring a pocket microscope. But the reason for all this at once became evident when the Darwinian doctrine showed that it is in these embryonic characters that relationships are to be discovered and that it is in later development that differences occur. As Haeckel has shown the embryos of the tortoise, the dog, the fowl and the man are all nearly alike in the early stages of foetal life (Figs. 1, 2, 3 and 4), utterly different as these creatures may be when they have attained their full development—the Darwinian doctrine has thrown a flood of light on the relationship of plants and animals, and shows us that when animals have got as it were on the wrong track however far they may go in it, they never come to anything very good.

FIG 5

hypotheses and by ideas of cycles and epicycles which must have burdened the astronomer's memory to the last degree. So soon, however, as the sun and not the earth was recognised to be the centre of our system the whole of the observed facts were seen to be in complete harmony and the relationship, comparatively speaking as simple as A B C. In our own time we have seen somewhat similar occurrences in regard to the relationship of animals and plants or I might shortly say, of all living creatures to one another. It used to be assumed that the highest plants and highest animals were to be compared together but all attempts to make this comparison rationally were unsuccessful, and it was only when an old member of this Society Mr Charles Darwin, pointed out that animals and plants had sprung from one common ancestor and had diverged in different directions that the various relationships became intelligible. I well remember that when learning botany it puzzled me

Nobody expects much of a jelly fish. Its soft, pulpy substance is incapable of anything but the simplest movement, and no animal that has not something hard to steady it can greatly excel the jelly fish. The soft molluscs which use their hard casing only for protective purposes, like the oyster and the snail, are bound to stay low in the scale of existence, and the highest mollusc (the octopus) appears to be striving after something better, but only by the aid of an attempt at a skeleton—the so-called cuttle-fish bone. But this has no joint in it, and even the octopus does not amount to much. Articulata with their jointed skeletons have reached such a pitch of social organisation as to be held up for examples to mankind, and ants and bees are regarded by some as almost the mental equals, if not the superiors, of some of the savage tribes of mankind. But the outside skeleton is a sore disadvantage for the animal must either remain without growing in size, or else it must be periodically

cramped for room, and periodically burst its shell, leaving itself naked, weak and defenceless. The right thing to do is evidently to do like the vertebrata, and have the hard parts inside, and the soft parts outside, but the relationship of these parts is a sore task upon the student's memory, and to many a one anatomy is a burden too heavy to be borne and the unfortunate youth is forced by it to leave the study of medicine and turn his attention to some easier pursuit.

Now, I think that with a little trouble one may find a way of linking anatomical relationships together in a more rational way than that of "Bodfi," a word which in my student days was used as a mnemonic to describe the form of the hippocampal convolution of the brain—backwards, outwards, downwards, forwards and inwards. The word also served to describe the course of the ribs, but Dr Anderson Stewart has shown us how naturally the peculiar twist the ribs take in a man arises from his upright position. Taking a circular steel hoop, and simply hanging it up by one side, he shows that it

FIG 6

Diagram of shoulder joint, to show the capsule.

FIG 7

Diagram of ligaments of phalanges—a capsule and lateral ligaments.

assumes an oval shape, like that of the thorax of animals going upon four legs and whose ribs hang vertically from the spine. On raising this up by one point it becomes twisted upon itself and takes precisely the peculiar bend which the ribs possess in man. The advantage of a naturally jointed skeleton is so obvious that I need not further discuss it here, nor need I discuss the texture of bone which has been so admirably treated of by my friend Dr Donald MacAlister of Cambridge. (Fig 5)

The ligaments and the joints were to me most puzzling until Dr Joseph Bell pointed out to me how very simple they were. What is wanted in a joint is a capsule to go round it so as to hold the ends of the bones together and prevent the synovial fluid from oozing out. If the bones have to move freely in all directions they must have a ball and socket joint, as at the shoulder (Fig 6) and at the hip, and there you will

FIG 8

Diagram of the ligaments of carpus as seen from behind. Besides these there are ligaments passing in various directions so as to bind the bones more firmly to each other.

are a simple capsule because it cannot be particularly strengthened at one point or another without interfering with freedom of movement. In the case of a hinge-joint, such as those of the fingers or toes, elbows or knees, you will have the capsule remaining thin at the front and back so as to leave the movement free, but you will have it strengthened at the sides so as to tie (Fig 7) the bones more firmly together, and the stronger parts are called lateral ligaments. If several bones have to be connected each one must be tied first of all to the one nearest it, and then two or three must be tied together at a time, and in this way we get the network of ligaments which we find at the wrist and tarsus (Fig 8). The same thing is true

of muscles and, as Professor Goodser used to point out the muscles of the back, so perplexing at first, are really quite simple in their arrangement. For each of the spinous vertebrae has to be bent and straightened and has also to rotate more or less upon its neighbours, so as to allow the upper part of the body to swing round upon the lower. We have therefore muscles going from the spine of one vertebra to the spine of the next, and then muscular strips stretching over a few and then over many vertebrae, so as to straighten the spine either in part or whole, as the movements may require. A similar arrangement holds good for the muscles passing from the spines to the lateral processes and which rotate the vertebrae on one another.

But if we are to group the muscles and nerves of the body into one easily remembered whole, we must see what is the chief function to be subserved by them, what is the centre of the little universe which they compose. The function of most imperious necessity is respiration. A man may starve himself to death, but he cannot kill himself by holding his breath. He may refuse food, but he cannot refuse air. In the child the function of respiration is the first which evidences itself after birth, and the muscles which subserve it are more fully developed and more perfectly innervated than others. The nerve channels which supply them are, as it might be termed, more deeply grooved than others and it is along these channels that superabundant energy overflows in the movements of laughter which evidence joy. This has been very fully and wisely explained by Herbert Spencer in his essay on "Laughter." But the great poet, whose recent death the whole civilised world is now deploring, has classed together in a few pregnant words the channels through which the overflow of energy may run in their proper order. In describing the joy evinced by a baby on seeing its mother, Tennyson says it

"began
A blind and babbling laughter, and to dance
Its body and reach its falling innocent arms
And lazy lingering fingers."

The very parts which attain to the highest development in adult age and are capable of the finest and most dextrous movements, are the last to develop, and in infancy they are well described as "lazy lingering fingers." They take no part in the function of respiration, but they are of the utmost utility in the function which comes next to respiration in importance—namely, that of nutrition. The animal has to be fed, and all the arrangements of the limbs are more or less subservient to this primary object. In a fish the muscular masses at both sides of the spine bend the posterior part of the body and the tail alternately to one side or another, and so the animal is propelled through the water in search of food. No doubt these same muscles help it to escape danger, but their primary object is to obtain food, and if there be great hunger all animals will strive to feed, whatever be the risk they run in doing so. The movements of fish are simple compared with those of animals with limbs, and especially with those of man. Yet the arrangements of man's body are equally adapted with those of the fish for obtaining food.

There are two prevalent ideas regarding the origin of man. One is that he started full grown and perfectly developed from the dust of the ground, and lived in a garden which he "dressed and kept." The other is the Darwinian one, that man is developed from an arboreal animal like the monkey though lower than the monkey. It matters not which of these ideas we take, because they perfectly agree that primitive man lived at first in a kind of paradise where he was not exposed to the attacks of wild beasts, and where he fed on the fruit which he plucked from the trees around him. The story of Adam and Eve has got the advantage of not only being more poetical, but it is very much more easy to discuss the actors in the scene by the names of Adam and Eve, than by the terms "male" and "female frugivorous animal."

Let us take then the story from Genesis. One day Eve went into the Garden of Eden—saw an apple upon a tree—plucked it, ate it, and then went to get another for Adam. In trying to analyse the muscles concerned in these acts, the easiest way is to go to your bedroom, strip off your clothes, imitate Eve's action, and as you do so feel out the individual muscles as they contract under the skin. This plan of learning the muscles is one which I used to follow as a student of anatomy, and I found it a very useful one indeed. If you do this you will find the muscles of the neck, shoulder, arm, fore-arm and hand contracting successively or together in coördinated movements, which are beautifully adapted to

the purposes just mentioned. We might take the muscles which produce these movements one by one, but I think it is easier for the purpose of grouping them, though not so good for the purpose of study in your own room, to consider first of all the motor centres in the brain from which the stimuli proceed. Before proceeding to consider these I wish to draw your attention to the errors into which one may fall regarding the action of muscles as well as of the motions of the planets by regarding them from a wrong point of view. Thus, the action of the tensor vaginæ femoris is usually said to be that of rotating the thigh inwards upon the body and thus turning the foot and toes inwards also, an action which is denounced in all calisthenic exercises. But this muscle was not introduced into the body for the sole purpose of plugging drill sergeants and dancing masters. As the late Professor Sharpey used to point out, we ought to look at its action from the leg as a fixed point and then we discover its true uses at once. Place your hand at the side of the hip over the muscle and march forwards. You will then find that when one foot is planted firmly on the ground the corresponding muscle becomes tense whenever you lift the other leg and try to advance it. Whenever the other foot is raised the muscle rotates the body outwards on the fixed thigh and thus brings the centre of gravity of the person over the resting foot. If it were not for these muscles we should run a risk of falling down as we lifted one leg instead of balancing our selves with comfort upon that one which is resting upon the ground.

But we may now pass away from the muscles and nerves

FIG 9

Diagram of the motor centres in the brain modified from those of Ferrier and Horsley. The motor centres have been numbered so as to represent the successive actions in seeing, taking and eating the apple &c. 1. Eye sees the fruit (eyes turn to opposite side). 2. Looks more eagerly at it (head and eyes turn). 3. Turns towards it (head to opposite side). 4. Puts forth her hand to take it (a movements of shoulder b of elbow c of wrist d of fingers). 5. Luxuriatingly shuts her eyes so as to enjoy the sweet morsel more thoroughly. 6. Eats the apple. 7. Picks out and throws away the refuse (d movements of fingers e of index f of thumb a b c as in 5). 8. 9. 10. 11. Went and got another for Adam (8 movements of hallux 9 of small toes, 10, of knee and ankle 11 of hip).

to the nervous centres from which they receive their stimulus to action, and whatever doubt may exist in regard to the adaptation of the muscles to the peripheral nerves and the action of plucking and eating the apple, I think there can be no doubt at all that such an arrangement exists in the motor centres of the brain. These centres were localised in the monkey by Ferrier, and it is the difficulty I have had in remembering their position that has led me to arrange them in accordance with some definite movements in a series of actions to which I have found they corresponded. If we start from the posterior part of the second frontal convolution pass upwards along it and then across to the ascending frontal convolution, follow this downwards parallel to the fissure of Rolando, and then turning the end of this fissure ascend again upwards along the parietal convolution which lies behind the fissure, we find (Fig 9) that the centres are arranged in the very order required for looking at the apple stretching out the hand to take it, bringing it to the mouth, separating the seeds and throwing them away. The aim and object of the whole series of actions is to eat the apple. And that the centres

for doing this are situated exactly where we should expect them—at the very end of the fissure of Rolando. In Ferrier's description we know that the movement which brings the hand to the mouth appears to be repeated on both sides of the fissure of Rolando but it appears that the part anterior to the former would bring the hand to the mouth with the apple, while the part situated behind the fissure of Rolando would throw the remnants of it away. And here comes in a very interesting point in order to complete the series of actions necessary for Eve to go and get another apple for Adam you require movements of the leg (Fig 10), and these are not fully represented on the surface of the brain. But they have been found by Horsley and Schäfer exactly in the place where, according to our idea, they ought to be, at the marginal convolution connecting the first and last centres of which we have just spoken and thus completing the circle of action.

Here I would like to draw your attention to the fact that great painters like great poets often appear to see more than ordinary mortals, and in his lovely picture, "The Fall of Man" which is painted on the walls of the Loggia of the Vatican in Rome, Raphael seems to have almost forestalled the results of physiological experiment. In the mental picture of the scene which most of us must have formed for ourselves it is probable that it did not occur to many of us to pay any attention whatever to the movements of the great toe, and yet in Horsley's diagram of the cortical centres that for the hallux comes forward most prominently, and, as you will see from Raphael's picture,¹ Eve's foot is raised, and

FIG 10

View of a lobe of the cerebrum from the longitudinal fissure after Horsley and Schäfer

the great toe both in her foot and that of Adam is brought into what one would think rather too violent action. In the action of plucking and eating the fruit there is no break between the eyes, head and arm, and that of the mouth and tongue, and in the usual process of eating the actions go on which are necessary simply to repeat the process of plucking and eating. Again, too, in the dog the arrangement is quite different (Fig 11), and yet it is exactly what one would expect from the different necessities of the animal. In the frugivorous animal the motions are pluck and eat, pluck and eat, but in the carnivorous animal a long chase after the prey is necessary before the animal can bring the jaws into action, and in the dog accordingly we find that the movements of mastication, instead of being arranged in linear series with those of the limbs, are represented at a spot which is somewhat removed from them. In the cortex the centres are so far apart as to be distinguishable from one another, but as the nerve fibres which pass downwards from them to the base of the brain become closely crowded together in the internal capsule localisation is more difficult (Fig 12), although Horsley and Beever have found generally that the arrangement of the fibres from before, backwards, corresponds to the arrangement of the centres just described. But as the nerves pass out from the spinal cord to reach the muscles they again become separated and as Ferrier and Leo have discovered, the motor roots which enter into the brachial plexus are arranged with a view to

¹ We publish with this lecture a coloured reproduction of Raphael's famous picture of the Fall of Man with a view of illustrating for our readers the various points referred to in this portion of the lecture.

definite coordinated movements. Now this plexus has been to me, and I think to many others, a perfect perplexity both in its anatomy and physiology. Yet if we take it from the same point of view as we have taken the motor centres it becomes comparatively simple. We must not forget that although the monkey is so much like man that we can draw most useful deductions regarding human physiology from experiments on these animals, we must not transfer without more ado the results of these experiments to man in their entirety. We must remember that man, although formerly a frugivorous and probably more or less arboreal animal, is now very different from a monkey, and experiments in the laboratory must be compared with and corrected by those experiments which disease makes upon man in producing local

FIG 11

Diagram of brain of dog after Ferrier. C.S., Crucial sulcus. 1, Movements of eyes, as if to see freely. 2 and 3, Movements of fore-leg and 4 of hind leg as in running. 5, Movements of tail requisite in turning quickly as when a greyhound is following a hare when it doubles. x x x Movements of mouth and jaws.

ised palsies. I think it very probable that many here would find it difficult to answer the question, What are the movements which result in the monkey from stimulation of the fifth cervical nerve nor might he be able to remember them six months hence even if he learned to night that they consist in the shoulder and arm being raised upwards and backwards, the humerus rotated outwards, the forearm flexed and supinated, the wrist extended and the tips of the fingers flexed. But he would find it easy enough to remember them, not for six months only, but for the rest of his life, if he were told that they were simply those required to raise the hand in such a way as to grasp an apple hanging straight above him. If you go through these movements you will find that your

FIG 12

Diagram of the internal capsule

first impulse is to take a slight breath which is chiefly effected by the diaphragm, and on looking at the brachial plexus you find that the first branch which is given off from the fifth nerve is a filament to the phrenic (Fig 13). Then, just as you proceed to raise your shoulder, you take a still deeper breath, and this, too, is represented in the plexus by the posterior thoracic nerve, starting from the fifth and sixth nerves and going to the serratus magnus which has little power to raise the ribs and act as an inspiratory muscle while the shoulder is depressed, but will do so when the arm is raised. If your hand is hanging by your side you will find the shoulder slightly drawn backwards by the rhomboid and the arm rotated a little outwards by the infra spinatus, which is

supplied by the supra scapular nerve. Next you raise your arm and as you do so you will find that unconsciously you bend it and turn it out, you extend the wrist and flex the fingers. The raising of the arm and turning it out is effected by the deltoid and teres minor, which are innervated by the circumflex nerve, while the shoulder is still further raised by the trapezius which gets its nervous supply from a higher source—the spinal accessory. The biceps and other flexors of the arm receive their supply through the musculocutaneous nerve from the outer cord. In the movements of the wrist and fingers the fifth and sixth nerves appear to coöperate and those of the fingers are chiefly due to the sixth. The supinators and extensors of the wrist, fingers and thumb get their nerves from the musculo-spiral or its interosseous branch. To resume, the fifth and sixth cervical nerves raise the shoulder, flex the forearm and extend the wrist. The nervous energy passes from them along the upper trunk and outer cord of the brachial plexus to the flexors of the forearm, while the impulses to raise the shoulder, rotate the humerus and extend the wrist and fingers, travel chiefly through the posterior cord by the musculo-spiral nerve and its interosseous branch to the extensors of the wrist and digits. From the fifth and sixth cervical nerves we make a

FIG 13.

Diagram of the brachial plexus.

jump to the first dorsal, which has an exactly opposite action. The movements it produces are that the hand closes firmly upon the apple, the wrist is twisted round into the prone position and flexed to the ulnar side. The forearm is extended, and the upper arm is retracted in the manner required to pull the apple from the tree. In these movements if you put your hand upon your chest you will find that the pectoral muscles are largely engaged, and they receive their nerves partly from the internal cord of the brachial plexus. Flexion to the ulnar side is produced by the ulnar nerve, and the dragging of the arm down is effected by the subscapular, teres major and latissimus dorsi muscles, which are supplied by the subscapular nerves, and the triceps by which the arm is extended gets its nerve supply from the musculospiral. But these movements, especially if executed forcibly as they would be if the apple were firmly attached, would bring the hand below the level of the mouth, and the prone position would keep the apple away.

We must now go back to the sixth cervical nerve which we find will rectify this action for it raises the arm in and upwards with the forearm flexed so as to bring the hand to the mouth, supinated, and with the wrist and basal pha-

langes extended, so as to present the apple comfortably for eating. In effecting this movement the nervous impulses travel by the posterior thoracic circumflex, musculo cutaneous, musculo spiral and median nerves to the serratus magnus, deltoid, biceps, brachialis anticus, supinator longus and extensors of the wrist and basal phalanges. The position of Adam's left hand in Raphael's picture shows this action in its middle stage before it has carried the hand to the mouth. The four last phalanges of his fingers are flexed and we may suppose that the flexion is effected by means of the median nerve, but it is just possible that their flexion may be due to mechanical pulling on the tendons by the extension of the wrist and basal phalanges just as the hand is opened in the well known schoolboy trick by bending the wrist forcibly inwards, and thus mechanically stretching the extensor tendons of the fingers. In this picture the action of the serratus magnus muscle in drawing forward the shoulder and rotating the scapula so as to raise the shoulder is well seen and the action of the muscle appears almost exaggerated. We have already found that it gets a branch from the fifth nerve as well as from the sixth. We may fairly suppose that the branch from the fifth is the channel for the impulses which cause the muscles to act as an inspiratory muscle when raising the arm to pluck the apple, while that from the sixth serves to excite the muscle to pull the shoulder forward. Now, here we have got apparently the movements required for plucking the apple and conveying it to the mouth and yet we have got two nerves which seem superfluous—the seventh and eighth cervical. We may suppose the seventh to be brought into play later on, when the first pair recognised their nakedness, for its action in the monkey is to bring the hand over the pubis in the position of Eve's, as represented by Raphael in the expulsion from Paradise (Fig 14). We cannot in this scheme find the place for the eighth nerve in the entirety of its action, as observed in monkeys, but the first part of the movement which it produces may be used in throwing away the refuse of food.

FIG 14

Expulsion from Paradise, after Raphael. The position of Eve's right hand shows the action of the seventh cervical nerve

The mere fact that I have been unable to work this last nerve properly into this scheme shows you how imperfect it is, yet I trust that as an attempt to hang together the facts anatomical and physiological, it may not be without service as an aid to your memories, and still more as an inducement to you to find out the true relationships of the different parts of the body, such as those of the lumbar plexus and the anastomoses of the vagus and sympathetic. But you will say to me that, although anatomy is doubtless hard, *materia medica* is to some people even harder, and the dry details less interesting to many a student even than those of anatomy, while they have not the merit of possible utility to recommend them. You may ask me if I cannot show you some way of easing the burden of *materia medica*. With such a request I deeply sympathise, and if I had my way I should sweep away the whole subject of *materia medica* as understood in some places, although not, as I believe, understood here and replace it by pharmacology, therapeutics and practical pharmacy. Therapeutics, the cure

of disease, is the aim and object of medicine, except in so far as prevention is concerned. A patient comes to you for relief of his discomfort or pain, for restoration of his health or prolongation of his life, and it matters but little to him whether you can describe the microscopic appearances of his various organs, if you cannot afford him any help. But it is little or no use to know the mere names of the plants whence drugs are derived, more especially as these names vary from one Pharmacopœia to another, while the plant remains the same and the change of name in the Pharmacopœia does not alter its action in the least. It is useful for the druggist to recognise a medicinal plant, though it is but little use for the physician. But it is of great importance that you should be free from the reproach of 'pouring in drugs of which you know little into bodies of which you know less', that you should thoroughly know pharmacology and have a clear understanding of what your drugs will do, so that you may know precisely what to give and when to give it, when to increase your dose and when to withhold your medicine entirely. Pharmacology and rational therapeutics are inseparable and without the former the latter is impossible. It is also very important that you should know how to prescribe efficiently, and this can only be learned in a practical course, in which one can become acquainted with the qualities and interaction of drugs in such a way that when they are mixed they will not form disgusting, inert or dangerous compounds. It is clear that this part of the subject is closely connected with chemistry and botany and as a subject of examination should come as close after them as possible, while it is obvious that the action on the healthy body or pharmacology and that upon the diseased body or therapeutics can only be understood after one has learned the functions of the body in health and their modification in disease. But even were the whole of the *materia medica* (understanding by this term the origin and physical characters of drugs) swept away the subject of pharmacology has grown so large that it is exceedingly hard for a man to remember the actions even of the most important drugs, and the only way of rendering it possible is to have them grouped together, so that one description will do for many drugs which vary from each other only in a slight degree.

Attempts at such a classification have been made by Buchheim and his scholars and before very long, I think, it is very likely that the arrangement will be much simplified. Drugs after all, are things which act upon the organs of the body and upon the substances which compose those organs. What these components are we may see readily from a glance at the food required to renew them as they waste away, and a typical meal consists of a beefsteak with fat or butter, bread or potato, salt and water. The albumen of the beefsteak would chiefly be represented in the muscles and glands, while fat is found largely in the brain or nerves, and carbonates salt and water occur everywhere throughout the body. In classifying drugs we find that some of them act more particularly upon the albuminous and others upon the fatty principles of the body, while others affect both. With such a division we may group each of the drugs that act upon our muscles and those that affect the nervous system, afterwards subdividing them according to the particular kind of action that they exert and the principal parts of the muscular, nervous or glandular systems which are chiefly acted upon. Thus, as Professor Harnack has pointed out, nearly all drugs which act as emetics have likewise the power of paralysing muscles when locally applied, and, as I indicated about two years ago, the whole class of cardiac tonics which cause contraction of the frog's heart, with stoppage in systole, are also more or less local anaesthetics. One group, containing physostigmine, muscarine and pilocarpine, stimulates secretion and causes contraction of involuntary muscular fibre, while another, containing atropine, hyoscyamine and hyosine have exactly the contrary action. In this group the action upon the nerves, the glands and involuntary muscular fibre is well marked. In the lowest of the group, atropine, there is little hypnotic power, in hyosine this power is greatly developed, and in so far as we get the connexion with another group—viz., that of morphine. Morphine is almost a pure hypnotic, but if we take the alkaloids of opium, we shall find they form a series in which the hypnotic power becomes less and less, while the tetanising power becomes greater and greater, until at last in thebaine we have a substance which acts almost like strychnine. In cannabis indica we have the same thing, though to a less extent, for cannabine is hypnotic and cannabi tetanin is

strongly convulsive. It seems very strange that you should not only get such well marked diversity of action in the alkaloids of the same plant, but should sometimes, as in jaborandi, find that two alkaloids, pilocarpine and jaborine, are almost completely antagonistic. This curious condition has been rendered much more intelligible by the admirable researches of two former presidents of this Society (Professors Crum Brown and Fraser) whose work has also afforded a basis for a rational knowledge of the relationship between chemical structure and physiological action. They showed that methylating strychnine converted it from a convulsing into a paralyzing poison.

But there is another very strange point to be considered—viz., that many, if not all, drugs have an entirely different action in small doses from what they have in larger ones. This and the tolerance of drugs are exceedingly difficult to understand. The extent to which tolerance is earned is sometimes incredible. Although the subcutaneous injection of a grain of morphine would be certainly very dangerous, if not fatal, to any one of us, yet I have seen a case in which the daily dose of morphine injected subcutaneously varied from twenty-five to thirty-two grains. Now I cannot explain this—I can only throw out as a suggestion that the explanation is to be found by considering the action of the drug upon individual cells. I need not here discuss the nature of the cell. This has been done very much better than I could possibly do it by Sir William Turner. But I would remind you that both aniline colours and drugs have a tendency to fix upon one part of a cell rather than another. In addition to this selective action it is evident that they will come in contact with the surface of the cell sooner than with its interior, and if they be supplied to the tissues in a small quantity they may affect the surface of the cell only. One of the best examples of tolerance that I know is that of a salmon coming from the sea into fresh water or from fresh water into the sea. The cells of its gills become gradually inured to the presence or absence of salt during the passage of the fish through the brackish water. You can readily see that at first only the external part of the cell would be affected by the salt and the sudden application of a strong solution might destroy the balance between the outer and inner parts of the cell and thus destroy its life. But by and by the whole cell would participate and the amount of the salt could be gradually increased to a great extent without greatly disturbing the balance between the interior and exterior of the cell. In the same way a small quantity of morphine coming in contact with the external part of the brain cell only, might greatly modify its function, while if the cell was, as it were, thoroughly soaked in the poison an enormous quantity of morphine would not make such a difference between the interior and exterior of the poisoned cell as a small quantity would do in the case of the unpoisoned one. Such a subject as immunity from poison is excessively interesting more especially as now we are beginning to see that immunity from disease may in some cases at least depend on the power of the organism to resist the poisons formed by microbes. But I have already trespassed too long upon your time, and I must conclude. You may possibly think from what I said at the beginning of this paper that I wish to abolish examinations. I do not, because I look upon them as a necessary evil, but I should wish greatly to modify them and to render them more a test of a man's capacity for applying his knowledge than of his simple memory for facts. When I was in India three years ago I was told of a native medical student who had been brought before his examiners for copying. He denied the charge, but the examiners said, "How is it possible that you could reproduce page after page of a text book verbatim unless you had copied?" The student replied, "I will do it again if you will give me pen, ink and paper" and he did so in the presence of the examiners. Yet although he reproduced the text book verbatim the knowledge that such men as he have is generally useless, they could not put it into practice, and although they may write down a whole treatise on surgery, they will sometimes stand helpless when called upon to do a simple operation. It is just a little over thirty years ago that I attended Professor P. G. Tait's course of Natural Philosophy, and his examinations seemed to me to be perfect models of what examinations ought to be. As an example I may give one of his questions. Suppose a tumbler filled with water with a cork fastened to the bottom inside were equipoised on a balance would the scale containing the tumbler fall or rise if the string were cut and the cork allowed to come to the top of the water? The answer given by some was that the tumbler

would be heavier, because the cork would no longer be trying to get to the top of the water, and thus pulling up the tumbler. For this Professor Tait gave nothing. Others, of whom I was one, said there would be no change, because nothing had been added to or taken from the tumbler. This answer was allowed full marks, but not a man in the class gave the complete answer, which was that the tumbler would be heavier, because if the string was cut, the space at the bottom of the tumbler would be filled with dense water instead of light cork, and thus the greater mass being nearer the centre of the earth, would be multiplied by the greater attraction while the lesser mass of the cork would be multiplied by the lesser attraction. Now, demand creates supply, and the questions set by an examiner tend to raise the standard of knowledge in the student, but supply may also create demand, and just as an article previously unknown when presented to the public may take readily, so knowledge possessed by a student may lead to the improvement of examinations. At present it would be hopeless for an examiner to put such a question as this to a medical student: "Describe the relationship between atropine, morphine and strychnine, mention the chemical changes required to convert a convulsing into a narcotic poison and *vice versa*, and tell from the chemical structure of an alkaloid, of which the structural formula is given, what its physiological action must necessarily be." And yet such a question as this will, I have little doubt be perfectly fair some years hence. At present it would be absolutely useless to put it, because one could not get an answer to it. You will not find an answer in any text-book and very probably you will not find a single man living who can answer it thoroughly, but it is just for such a Society as this, composed as it is of men of keen and active brains with overflowing energy, ever ready to propound a theory of their own or demolish one proposed by others, and willing to do experimental work for either the one or the other purpose—it is for such a Society as this and for such men to provide that knowledge which shall make such questions possible, and when they are possible we may hope that the time is not far distant when medicine will no longer be an art, but will become a science.

Clinical Lecture

STERNO-MASTOID TORTICOLLIS

Delivered in the Theatre of St Thomas's Hospital on
Dec 8th, 1892,

By WILLIAM ANDERSON, F.R.C.S. ENG

THE names torticollis, caput obstipum¹ and wryneck, like many others in surgery, merely express a symptom without suggesting anything as to the pathological nature of the condition designated. In their wider signification as a rotatory distortion of the neck they may indicate a merely temporary malposition of spasmodic or rheumatic origin, or secondary to certain defects of the muscular apparatus of the eye, or to inflammatory and other tumours in the neck, or a permanent affection due to disease of the vertebral column or cicatrization after injuries attended by loss of substance in the integumentary structures, but the terms when unqualified usually imply a special contraction arising from a defect in the sterno-mastoid or much more rarely, in other muscles of the neck. It is to the sterno-mastoid torticollis that this lecture is devoted.

The familiar form of wryneck is well illustrated by the patient upon whom I operated a few days since, and a recapitulation of the details of this case will serve as an account of a typical example. The patient was a girl aged seventeen, of healthy aspect but of small physique. The deformity had existed from birth, but there was no history of any difficulty in connexion with delivery or of a sterno-mastoid tumour observable afterwards. The neck was flexed and lateralised towards the right side, the face looking directly

¹ *Davus sili comicus atque
Stes capite obstipus*—Horace, Sat. li. v

forwards and rotating easily towards the left, but could not be turned in the opposite direction. The right sterno-mastoid was sharply defined especially during the movements of the neck, and its muscular belly appeared to be smaller as well as shorter than that of the opposite side. The right shoulder was slightly raised. On looking at her face from the front there was a marked asymmetry, the right eye being about a third of an inch below the level of its fellow, and the whole of the right side of the cranium and face smaller than the left. The spine showed a slight but distinct double curvature with a concavity in the cervical and upper dorsal region turned towards the affected side, and a compensating dorso-lumbar flexure in the opposite direction below. There was no alteration of the visual axes and none of the dysphagia occasionally noted in severe cases.

Here the diagnosis of a congenital or infantile sterno-mastoid torticollis was very easy. The permanency of the distortion and the presence of cranial asymmetry proved that it was not a spasmodic condition. The splenius, scaleni, trapezius, platysma and other muscles which are occasionally the seat of changes leading to a torticollis appeared to be normal, and there was no reason to believe that any other muscle besides the sterno-mastoid was implicated farther than by the small but inevitable adaptive changes that occur in connexion with long continued malposition of the parts. Finally, there was no tumour on the neck and the cervical vertebrae were not diseased. To contrast with this case I may mention a patient who presented herself here a short time ago and who may have been seen by some now present. This was a young girl aged sixteen, who complained of a torticollis of six months' duration. Her left sterno-mastoid was in a state of strong contraction, producing a deformity very similar to that just described, but there was no facial or cranial asymmetry, and on examining the neck more closely the trapezius of the same side was found to be also contracted. We had here to deal with a condition of spasm propagated to the muscles through the spinal accessory nerve, and on administering an anæsthetic the deformity immediately disappeared.

The characters of sterno-mastoid torticollis are sufficiently pronounced to fix the attention of even an unscientific observer, and there can be no doubt that the affection is not a modern one, but curiously enough it is not described by any of the ancient writers, although it must have been quite familiar to them. The first reference to it, so far as I have been able to ascertain, was in the works of the Dutch physician Tulp (whose features have been immortalised in Rembrandt's "Lesson in Anatomy"). He mentions an example of the deformity and its cure by a surgeon of whom nothing remains except the Latinised version of his name—Minnius, and it is interesting to hear that Minnius had gained a reputation for treatment of such cases, as this makes it probable that there were in those and older days surgical specialists for the cure of wryneck, just as there were specialists for hernia, stone and many other conditions with which orthodox surgery was often afraid to meddle. Cases were also quoted by Tulp's pupil Meekren and by his friend Roonhuijze, but it was not until the last century that the complaint became an item in the surgical text-book, and even Samuel Sharp, writing about 1740, did not consider that congenital wryneck ought to be treated by the knife. It was in fact only with the great French surgeon Dupuytren that the serious consideration of the surgery of the disease began.

At the present day we know a good deal about torticollis, but there is still a great deal that we have to learn. We have a mass of experience as to the phenomena and treatment of the affection, but its pathology is still involved in obscurity and disputation. It is known that the characteristic deformity is seen at birth or very shortly afterwards, though there is still a lack of precise observation on this point, and there can be no doubt that in a considerable proportion of cases the condition has arisen during intra uterine life. It is more common in girls than in boys, three or four times more frequent on the right side than on the left, and is almost invariably single. There have been four theories of causation framed to account for it, three dealing chiefly with cases of truly congenital wryneck and one touching only upon those in which the foundation is laid by an accident of parturition. One view attributes it to a simple arrest of development in the face and neck. A second traces it to a disease of the nerve centres affecting the side of the neck secondarily, but as the nature of the disease has not been explained the hypothesis is at least a very incomplete one. A third, and perhaps the oldest,

view regards the shortening of the muscle as the result of a vicious position of the head of the foetus *in utero*. A similar hypothesis has been offered in the case of club-foot and other deformities, but it appears very unsatisfactory, for if the mere attitude of a part during intra uterine life could determine a permanent shortening of the muscles relaxed by the posture scarcely a joint in the body would be free from distortion at birth. A fourth explanation, advanced by Stromeyer, assigns as the essential cause a laceration of the muscle during parturition, an accident that is said to be particularly liable to occur—although we do not know in what proportion of cases—in breech and foot presentation, in which the parts about the neck are subjected to a good deal of stretching in the course of delivery. This theory is very plausible, but the evidence connecting the two conditions is still far from complete. The out-patient room has afforded us many examples of the so called congenital tumours of the sterno-mastoid, which were formerly supposed to be of syphilitic origin, but are now, and probably with justice, believed to be due to an effusion of blood in the sheath of the muscle and consequent upon a rupture of some portion of the muscular belly. Given such an accident, a permanent defect of the muscle appears very probable, but few, if any, of these cases have actually been traced on to a sequent deformity, and Jannet and Petersen have brought forward arguments to show that such an injury never leads to wryneck. Moreover the investigation of the history of a case of torticollis seldom if ever eluces any clear account of an antecedent sterno-mastoid tumour. At present we can only believe that a very small proportion of the examples are due to this accident.

A few words may be said as to the comparatively rare cases of acquired sterno-mastoid torticollis. Syphilitic myositis undoubtedly explains a few. Tumour of the muscle may in like manner cause more or less distortion of the neck, as in the case of spindle-celled sarcoma that recently left the hospital. There the entire muscle was excised with the growth and the wryneck disappeared, and it is worthy of note that the unbalanced action of the opposite muscle has not set up any deformity. Traumatic injuries to the muscle may in like manner induce torticollis, but the cases are very rare.

The treatment of sterno-mastoid torticollis is conducted upon principles similar to those which guide us in dealing with other myopathic deformities. In the slighter cases, if observed sufficiently early, a cure may often be effected without operation by persevering manipulation of the head aided by the use of a suitable apparatus, but the majority of examples brought under the notice of the surgeon require the section of the affected muscle or its tendon.

The earliest operation on record—that of Minnius in the case reported by Tulp—consisted of division of the muscular fibres of the sterno-mastoid by an open wound, the section being very carefully performed, we are told, in order to avoid injury to the carotid artery and jugular vein. The section of the muscular belly has been revived in recent years and many surgeons have spoken very highly of the results. I have performed it only on one occasion, and although the experiment was perfectly successful and the immediate effect was decidedly greater than after section of the tendon I have not cared to repeat it. The almost immediate relaxation of the carotid sheath to the deep surface of the muscle increases the danger and difficulty of the operation, a scar is left in an exposed situation and the portion of the muscle below the line of section will in all probability undergo atrophy in consequence of the section of its nerve. If this plan be set aside only one other seat of operation remains, the tendons of origin, because the division of the muscle near the base of the skull, although possible and not dangerous, would involve a large wound and would offer no compensating advantages.

The section of the tendons of origin was performed in the seventeenth century by Flurianus, a Dutch surgeon (whose name, like that of Minnius, exists only in its Latin form), the instrument used being a sharp pair of scissors, and Samuel Sharp in the last century described an open operation for the same purpose, but as he regarded it as unsuitable for long-standing or congenital cases it was little used. It is probable, indeed, that most cases of wryneck were either treated with apparatus or neglected altogether, until the example of Dupuytren and the powerful advocacy of Dieffenbach and Stromeyer led to the subcutaneous method, which thenceforth held its ground unchallenged until antiseptic surgery brought the original plan again to the front.

In the milder cases of wryneck the sternal head alone requires division, and for this there can be no doubt that the

subcutaneous operation is advised by Dupuytren is the best. It leaves only a minute scar, and if it be recollected that this portion of the tendon is attached to the front of the sternum well below the upper border of the bone and that it is isolated by a complete fascial sheath it will be seen that its division is both safe and easy. An open wound here could give no advantage.

When the clavicular head is also involved the question of operation becomes more complicated. It will be remembered that this tendon arises from the upper border of the inner third of the clavicle, while the muscular fibres connected with it are divided into two separate bundles, one passing to the mastoid process (cleido-mastoid), the other to the occipital bone (cleido-occipitalis). Immediately behind it is a well marked cellular interspace containing some fat and connective tissue, with the anterior jugular vein passing to its termination in the external jugular trunk and a small branch of artery, usually from the supra scapular, which eventually pierces the interval between the two heads of the muscle and supplies integumental structures. The posterior boundary of the space is formed by a sheet of fascia enclosing the sterno-hyoid and omo-hyoid and filling up the triangle formed

was liable to infection. Antiseptic surgery has now however, placed it upon a different footing, and many surgeons, including Volkmann, Heinecke and Billroth, have given it their preference because it allows the immediate division of the fascial tissues which resist extension. The original operation of Samuel Sharp required a transverse incision through the skin of a size somewhat more extensive than the breadth of the muscle and about one-third of its length from the clavicle, a probed razor was then passed underneath the muscle and drawn outwards through the whole tendon, finally the wound was filled with dry lint to prevent the ends of the muscle from growing together. This procedure was amended by Benjamin Bell, who divided the tendon from without inwards, and it is his plan that is most favoured at the present day, the principal difference between the modern and ancient methods being the employment of antiseptic precautions.

The subcutaneous operation is usually practised by making a puncture at the inner or outer border of the clavicular head and introducing a blunt-pointed tenotome, the edge of which is turned outwards towards the skin. The section is then made in

THE ORIGIN OF THE STERNO-MASTOID WITH THE RELATIONS OF ITS TENDONS

RIGHT SIDE OF NECK.—A, Sterno-mastoid (cut). B Omo-hyoid. C Fascia investing the sterno-hyoid and omo-hyoid and filling up angular interval between them. E Clavicular head of sterno-mastoid with fascia. F Perforating branch of the supra scapular artery. d External jugular vein receiving anterior jugular and external tributaries. g Supra sternal vein running between layers of the sterno-mastoid fascia.

LEFT SIDE OF NECK.—I, Pectoralis major. K, M, Head of sterno-mastoid. N Clavicle. S Sterno-hyoid. T Omo-hyoid. U Sterno-hyoid. o Anterior jugular vein. p, Supra scapular vein. q Transversalis colli vein. r External jugular vein.

between these two muscles and the clavicle, to which the fascia is attached below. There is thus a kind of wall separating the seat of operation from the deep cervical and mediastinal spaces and from the great vessels and nerves of the neck, the inner portion of this being both muscular and fascial, while the outer part is composed of fascia only. At the outer border of the tendon is the external jugular vein, receiving the anterior jugular on the inner side and the transversalis lumen and transversalis coli veins on the outer side before piercing the deep fascial wall to enter the sub-clavian vein. From this it will be seen that the danger of wounding the large vessels at the root of the neck is very small, but both the anterior and external jugular are exposed to injury, and it is quite possible that the bleeding from either might be alarming. The small artery would probably give little trouble.

In dealing with the clavicular head the surgeon has the choice of two plans of operation by the open method and by subcutaneous section. The open method has the claim of antiquity, but there is no doubt that it was rightly abandoned in favour of its younger rival so long as the wound

the usual manner with a careful sawing motion, the finger being laid lightly on the skin opposite the point of operation. The sensation of yielding is very obvious and when the last fibres are cut a distinct separation of the parts is at once apparent. The amount of gain, however, is often rather disappointing because the fascial and other structures behind the muscle have undergone adaptive changes which enable them for a time to offer more or less resistance to extension, but these tissues do not offer any permanent opposition and the cure may always be safely completed by judicious after treatment. The internal puncture is believed to be safer than the external, as the anterior and external jugular veins are more out of harm's way than when the knife is introduced at the outer border of the muscle between the external jugular vein and the tendon. I have, however, adopted a modification of the latter plan, making a vertical incision of about half an inch in length over the outer border and dissecting down until the shining fibres of the tendon are exposed. The blunt-pointed knife may then be passed close to the deep surface of the tendon, preceded or not by a director, and the risk of wounding either of the veins is thus reduced to a minimum.

forwards and rotating easily towards the left, but could not be turned in the opposite direction. The right sterno-mastoid was sharply defined, especially during the movements of the neck, and its muscular belly appeared to be smaller as well as shorter than that of the opposite side. The right shoulder was slightly raised. On looking at her face from the front there was a marked asymmetry, the right eye being about a third of an inch below the level of its fellow, and the whole of the right side of the cranium and face smaller than the left. The spine showed a slight but distinct double curvature with a concavity in the cervical and upper dorsal region turned towards the affected side, and a compensating dorso-lumbar flexure in the opposite direction below. There was no alteration of the visual axes and none of the dysphagia occasionally noted in severe cases.

Here the diagnosis of a congenital or infantile sterno-mastoid torticollis was very easy. The permanency of the distortion and the presence of cranial asymmetry proved that it was not a spasmodic condition. The splenius, scaleni, trapezius, platysma and other muscles which are occasionally the seat of changes leading to a torticollis appeared to be normal, and there was no reason to believe that any other muscle besides the sterno mastoid was implicated farther than by the small but inevitable adaptive changes that occur in connexion with long continued malposition of the parts. Finally, there was no tumour on the neck and the cervical vertebrae were not diseased. To contrast with this case I may mention a patient who presented herself here a short time ago and who may have been seen by some now present. This was a young girl aged sixteen, who complained of a torticollis of six months' duration. Her left sterno-mastoid was in a state of strong contraction, producing a deformity very similar to that just described, but there was no facial or cranial asymmetry, and on examining the neck more closely the trapezius of the same side was found to be also contracted. We had here to deal with a condition of spasm propagated to the muscles through the spinal accessory nerve, and on administering an anæsthetic the deformity immediately disappeared.

The characters of sterno mastoid torticollis are sufficiently pronounced to fix the attention of even an unscientific observer, and there can be no doubt that the affection is not a modern one, but curiously enough it is not described by any of the ancient writers, although it must have been quite familiar to them. The first reference to it, so far as I have been able to ascertain, was in the works of the Dutch physician Tulp (whose features have been immortalised in Rembrandt's "Lesson in Anatomy"). He mentions an example of the deformity and its cure by a surgeon of whom nothing remains except the Latinised version of his name—Minnius, and it is interesting to hear that Minnius had gained a reputation for treatment of such cases, as this makes it probable that there were in those and older days surgical specialists for the cure of wryneck, just as there were specialists for hernia, stone and many other conditions with which orthodox surgery was often afraid to meddle. Cases were also quoted by Tulp's pupil Meekren and by his friend Roonbuijze, but it was not until the last century that the complaint became an item in the surgical text-book, and even Samuel Sharp, writing about 1740, did not consider that congenital wryneck ought to be treated by the knife. It was in fact only with the great French surgeon Dupuytren that the serious consideration of the surgery of the disease began.

At the present day we know a good deal about torticollis, but there is still a great deal that we have to learn. We have a mass of experience as to the phenomena and treatment of the affection, but its pathology is still involved in obscurity and disputation. It is known that the characteristic deformity is seen at birth or very shortly afterwards, though there is still a lack of precise observation on this point, and there can be no doubt that in a considerable proportion of cases the condition has arisen during intra uterine life. A second traces it to a disease of the nerve centres affecting the side of the neck secondarily, but as the nature of the disease has not been explained the hypothesis is at least a very incomplete one. A third, and perhaps the oldest,

view regards the shortening of the muscle as the result of a vicious position of the head of the fœtus *in utero*. A similar hypothesis has been offered in the case of club-foot and other deformities, but it appears very unsatisfactory, for if the mere attitude of a part during intra uterine life could determine a permanent shortening of the muscles relaxed by the posture scarcely a joint in the body would be free from distortion at birth. A fourth explanation, advanced by Stromeyer, assigns as the essential cause a laceration of the muscle during parturition, an accident that is said to be particularly liable to occur—although we do not know in what proportion of cases—in breech and foot presentations, in which the parts about the neck are subjected to a good deal of stretching in the course of delivery. This theory is very plausible, but the evidence connecting the two conditions is still far from complete. The out-patient room has afforded us many examples of the so called congenital tumours of the sterno-mastoid, which were formerly supposed to be of syphilitic origin, but are now, and probably with justice, believed to be due to an effusion of blood in the sheath of the muscle and consequent upon a rupture of some portion of the muscular belly. Given such an accident, a permanent defect of the muscle appears very probable, but few, if any, of these cases have actually been traced on to a sequent deformity, and Jeannel and Petersen have brought forward arguments to show that such an injury never leads to wryneck. Moreover the investigation of the history of a case of torticollis seldom if ever reduces any clear account of an antecedent sterno mastoid tumour. At present we can only believe that a very small proportion of the examples are due to this accident.

A few words may be said as to the comparatively rare cases of acquired sterno mastoid torticollis. Syphilitic myositis undoubtedly explains a few. Tumour of the muscle may in like manner cause more or less distortion of the neck, as in the case of spindle celled sarcoma that recently left the hospital. There the entire muscle was excised with the growth and the wryneck disappeared, and it is worthy of note that the unbalanced action of the opposite muscle has not set up any deformity. Traumatic injuries to the muscle may in like manner induce torticollis, but the cases are very rare.

The treatment of sterno-mastoid torticollis is conducted upon principles similar to those which guide us in dealing with other myopathic deformities. In the slighter cases, if observed sufficiently early, a cure may often be effected without operation by persevering manipulation of the head aided by the use of a suitable apparatus, but the majority of examples brought under the notice of the surgeon require the section of the affected muscle or its tendon.

The earliest operation on record—that of Minnius in the case reported by Tulp—consisted of division of the muscular fibres of the sterno mastoid by an open wound, the section being very carefully performed, we are told, in order to avoid injury to the carotid artery and jugular vein. The section of the muscular belly has been revived in recent years and many surgeons have spoken very highly of the results. I have performed it only on one occasion, and although the experiment was perfectly successful and the immediate effect was decidedly greater than after section of the tendon I have not cared to repeat it. The almost immediate relaxation of the carotid sheath to the deep surface of the muscle increases the danger and difficulty of the operation, a scar is left in an exposed situation and the portion of the muscle below the line of section will in all probability undergo atrophy in consequence of the section of its nerve. If this plan be set aside only one other seat of operation remains, the tendons of origin because the division of the muscle near the base of the skull, although possible and not dangerous, would involve a large wound and would offer no compensating advantages.

The section of the tendons of origin was performed in the seventeenth century by Flurianus, a Dutch surgeon (whose name, like that of Minnius exists only in its Latin form), the instrument used being a sharp pair of scissors, and Samuel Sharp in the last century described an open operation for the same purpose, but as he regarded it as unsuitable for long-standing or congenital cases it was little used. It is probable, indeed, that most cases of wryneck were either treated with apparatus or neglected altogether, until the example of Dupuytren and the powerful advocacy of Dieffenbach and Stromeyer led to the subcutaneous method, which thenceforth held its ground unchallenged until antiseptic surgery brought the original plan again to the front.

In the milder cases of wryneck the sternal head alone requires division, and for this there can be no doubt that the

dull on percussion, but elsewhere it was normal. There was no displacement of the apex beat or any evidence of hypertrophy or dilatation of the heart, the sounds of which were normal. Over the tumour (or pulsating prominence) there was a loud and harsh systolic murmur which was audible in front and also opposite the fourth and fifth dorsal spines behind. The diastolic shock was both audible and perceptible in front. On auscultation the breath sounds were normal over the right chest, but on the left side they were faint and somewhat tubular in character, and at the apex moist sounds were audible behind. (Fig 3) There were no other symptoms or indications of any importance. The patient remained in hospital from Sept 27th 1890, until his death on Jan. 18th following.

Treatment—The demand which the restriction of food, particularly of the fluid part of it, would make on the patient's

FIG 2.

fortitude was clearly explained to him and he expressed his willingness to submit to it. It was accordingly commenced on Oct. 7th, 1890 ten days after the patient's admission to hospital, the fluid part of his diet being then reduced to twelve ounces and the solid part to sixteen ounces. Ten grains of iodide of potassium in water, three times daily, were begun on the same day. Strict rest in bed, it is needless to add, was an essential point. The action of the bowels was aided, when necessary by the use of laxatives. Occasionally, when restless or sleepless bromide of potassium was added to the iodide mixture. On the 20th the amount of fluid was reduced to ten ounces and on the 24th to nine ounces which consisted of two ounces of claret, two ounces of water and five ounces of tea. On the 29th the patient expressed himself as much better and as not feeling reduced or weakened

FIG 3

by the restricted diet. The pulsating swelling beneath the clavicle was perceptibly smaller and no bruit was audible over any part of it. The diastolic shock had also disappeared. On Nov. 7th the patient was weaker and the juice expressed from four ounces of raw meat was added to his diet. No trace of the left radial pulse could be felt on the 17th and the impulse of the aneurysm was much less. A further addition some beef tea was made to the diet on the 27th. On Dec. 16th there was no tension in the right radial pulse and the left was still absent. The potassium iodide was omitted and a mixture containing per-chloride of iron, hydrochloric acid and tincture of calumba was substituted for it. The diet was now increased by the addition of bacon, fish, eggs and chops. From this date the

condition of the aneurysm continued to be in every way satisfactory, but the patient gradually grew weaker and he eventually died on Jan 18th, 1891. At the post mortem examination made by Mr Francis Croucher a tumour larger than a man's fist was found below the clavicle and behind the three first ribs and upper part of the sternum. The heart's substance was pale, no valvular lesion, much atheromatous degeneration in the aorta. Just above the aortic valves there was an aneurysmal dilatation about the size of a hen's egg and at the juncture of the ascending and transverse portions of the aorta a tumour commenced which involved the whole of the transverse and the first part of the descending portions of the arch. It was a large sacculated aneurysm containing a firm coagulum which almost entirely filled the sac. The inner surfaces of the manubrium, clavicle and first and second ribs were eroded. In the upper lobe of the left lung and just behind the aneurysm a large abscess cavity was found which contained fetid pus. There was no cavity in the right lung, but it was tuberculous in the upper lobe. The spleen was much enlarged and it also contained an abscess cavity full of blood stained pus.

Remarks—In this case phthisis was the cause of death. That disease was not diagnosed during life. The patient had very little expectoration, his cough was of the brassy character indicative of pressure on the trachea, and it became much less troublesome as the aneurysm reduced in size. The dulness of the upper lobe of the left lung was attributed to the presence of the aneurysmal sac, by which and its loud bruit the physical signs of the cavity that existed were completely masked. It is remarkable that so large an aneurysm, thus situated, gave rise to so few pressure signs.

CASE 2.—A man aged forty two was admitted to the Seamen's Hospital on March 21st 1892, and discharged on Oct 21st following. He stated that for twelve months he had suffered from pain in the right side of his chest and under the right scapula. He had a dry metallic cough and was subject to severe attacks of dyspnoea. There were no abnormal signs over the lungs, the heart's apex beat was in the sixth space in the nipple line, the impulse was heaving, the first sound was booming and there was no murmur. In the second and third intercostal spaces close to the right border of the sternum a pulsating prominence was seen and felt, over which a harsh and loud systolic bruit was audible and the diastolic shock was plainly perceptible. With the exception of his dry, harsh cough, pain and pulsation there were no pressure signs. The treatment was essentially the same as in Case 1 and need be only briefly recapitulated. On March 27th the amount of fluid was reduced to a pint, strict rest in bed was enjoined and potassium iodide in ten grain doses given thrice daily. On the 31st the dose of the iodide was increased to twelve grains and a half. On April 22nd the pulse was considerably reduced both in volume and tension, there was but little pain and the pulsation over the aneurysm was much less. The dose of the iodide was now increased to fifteen grains and the amount of fluid reduced to eight ounces daily. On June 10th the dose of the iodide was increased to twenty grains. On the 17th the pulsation of the tumour was very feeble, the area of dulness was decreased the murmur, though still audible, was much diminished in intensity, the diastolic shock had disappeared and the patient was free from pain, he had lost some flesh and the pulse was of low tension. On July 6th he was allowed to get up for an hour. On the 19th the restriction of fluid and the iodide were abandoned and a more liberal diet was allowed. The patient remained in hospital as a convalescent until Oct 21st, when he left at his own request. He was then practically well and said he felt quite well. The pulsation though greatly diminished was still perceptible and a soft bruit was audible. These were the only symptoms that remained. Since the patient left the hospital he has at intervals of about a fortnight presented himself for examination. He was last seen on Dec 23rd, 1892, when he was in good health and complained only of a little increase in the beating if he did too much. The pulsation and the bruit which at first became rather more pronounced after he left the hospital have not since increased. He has twice called to be seen and inspected during the last month.

Remark.—In both of these cases the administration of potassium iodide was combined with Mr Tufnell's method, for the reasons that in the first there was a clear history of constitutional syphilis and in both cases the aneurysms were situated so near to the heart that it was unwise to omit the use of a drug credited with the effect of slowing the blood current. Dr Douglas Powell in his admirable paper on Aneurysm of the Aorta published in vol. xiii. of

The external jugular can scarcely be hurt, and should the anterior jugular be punctured the bleeding may be easily arrested by a firmly applied compress.

In comparing the open and subcutaneous methods we must admit that for safety, precision and completeness the former is the better, but it has the disadvantage of leaving a scar that might be very objectionable in after years in the case of a girl. It would hence perhaps be better to preserve the subcutaneous plan for female patients—in whom the vessels are smaller and the risks of hæmorrhage less—and practise the open operation upon boys.

The operation completed and the wound dressed, the important question of after treatment arises, for by no method of section can the deformity be immediately righted, and we must always be dependent for the complete restoration of symmetry upon measures which stretch the structures that our operation has left untouched—the muscles, ligaments and fasciæ that have adapted themselves to the contracted position of the neck. As a rule it is desirable to leave the parts undisturbed and without any extension apparatus for a week after the tenotomy, and then the completion of the work of cure may be undertaken and carried out perseveringly for two or three months. We have for this end a variety of mechanical appliances and of exercises in which both surgeon and patient can play their parts. Firstly, with regard to apparatus, the embarrassment of choice is somewhat serious. Such a terrible complication of cuirasses, gorgets and helmets, with screws and straps and buckles and bars and ratchets, has been appended to this innocent little neck section that their representations in the catalogues of the French and English instrument makers suggest rather the defensive harness of a Crusader than the gentle agencies of coercion required to right a few recalcitrant muscles. Fortunately there are simpler means which achieve the desired end, and of these the simplest and the best is probably that recommended by Little. 'Apply a long strip of adhesive plaster around the forehead and occiput the maintenance in position being better secured by a bandage passed over the vertex and beneath the chin, the two being pinned together where the one passes over the other above the ears. Next attach around the waist a broader band of adhesive plaster, not so tight as to interfere with the movements of the ribs, over this a turn or two of calico roll or bandage, the two should be fastened together by a stitch here and there. The surgeon has now two circular bandages—the one around the forehead and the other around the waist, which are not likely to slip if properly applied. He should then sew a strip of tape to the head bandage directly above the ear of the unaffected side and carry it diagonally across the trunk to the opposite side of the waist bandage and there pin it. By this means the left mastoid process (we are speaking of wryneck caused by contraction of the right sterno mastoid) will be drawn towards the right sterno-clavicular articulation the original wryneck will be removed and the chin brought to the median line, or in young and flexible subjects even across it towards the affected side, constituting a wryneck in the opposite direction.' This I have found so satisfactory that I have in recent years adopted only one other method—that in which apparatus of all kinds is discarded, and in suitable cases—that is to say, in patients who are old enough and have the will and power to assist in their own cure—the latter plan which is followed by Mr Edmund Owen and others, is very successful. The patient is directed to carry a weight in the hand of the affected side in order to bring down the clavicle, and to practise sedulously the rotation of the face towards the right shoulder (in right side contraction), with the ear downwards towards the left shoulder and the neck extended, the exercises being tried before a mirror and repeated as often as possible. At night he is advised to sleep on the affected side with the head resting upon a high pillow. In addition passive manipulation is of great value and should be carried out daily by the surgeon or an assistant, the movements always aiming at the widest possible separation between the mastoid process and sterno-clavicular joint of the affected side. By these means we may always calculate upon restoring the neck to its proper line except in cases in which the operation has been delayed to a relatively advanced age—that is, twenty or upwards—and even in these a very great improvement may be looked for. The asymmetry of face, unfortunately, is not amenable to treatment, but it is certainly less conspicuous after the neck distortion has been relieved.

CLINICAL AND THERAPEUTICAL NOTES OF TWO CASES OF AORTIC ANEURYSM

By JOHN ANDERSON, M.D. ST. AND, C.I.E.,
M.R.C.P. LOND.,
PHYSICIAN TO THE SEAMEN'S HOSPITAL GREENWICH.

THE following two cases of aneurysm of the thoracic aorta seem to possess points of interest which render them worthy of record. In both cases the treatment followed was that laid down by the late Mr Tufnell of Dublin, combined with the administration of the potassium iodide, as advocated by Níclaton, Begbie, Roberts Balfour and others, and as far as the aneurysmal disease was concerned, the result was in each case satisfactory. The first case, however, terminated fatally from pulmonary phthisis, the symptoms of which were masked during the lifetime of the patient by those of the aneurysmal tumour. In the second case the disease was apparently cured and the patient was discharged from hospital with a greatly reduced area of dulness over the seat of the consolidated aneurysm, which had then lost its pulsation and murmur, and he remains up to the present time in good health.

CASE 1.—A man, aged forty eight, was admitted to the Seamen's Hospital on Sept 27th, 1890. No hereditary predisposition to any disease was traced in his family history. He suffered from primary syphilis, which was followed by constitutional symptoms, twenty years ago, and has indulged rather freely in alcohol. On admission he presented an anæmic appearance, and had of late lost flesh considerably—over 30 lb in weight, he stated, in the previous eighteen months (Fig 1). He complained of pains in the back, on the

FIG 1

left side opposite the fourth and fifth dorsal vertebra, he had a metallic cough, sudden attacks of dyspnoea which were of more frequent occurrence when up and walking about than when lying down, pain in the left shoulder, shooting down the inner side of the left arm and occasionally, to a lesser extent, down the right arm also. For the previous four months he had felt a 'beating sensation' in his chest under the left collar bone, and had noticed also that his voice had been more or less hoarse for two years past. No dysphagia.

Physical Examination.—His hair was turning grey and he looked older than his years, there was no difference in the size of his pupils, his left radial pulse was more feeble and of less volume than that of the right, but the beats were synchronous. His left hand felt colder than his right, both to other and to the patient himself. A pulsating prominence was obvious on the front of the chest beneath the inner half of the left clavicle, the superficial veins over the upper part of the chest were enlarged, especially those on the left side. The left jugular vein was very prominent, the expansion of the left chest on inspiration was limited, especially at the apex. (Fig 2.) There was marked dulness on percussion at the left apex extending from the middle line of the sternum to the middle of the clavicle, over an area the vertical diameter of which measured about three inches. The upper third of the left chest behind was also somewhat

ERYTHEMA OF THE FACE OF BUTTERFLY DISTRIBUTION

By THEODORE FISHER, M.D. LOND.,

REGISTRAR, ROYAL HOSPITAL FOR CHILDREN AND WOMEN, CLINICAL ASSISTANT, HOSPITAL FOR DISEASES OF SKIN, BLACKFRIARS.

THE following are brief notes of four cases of erythema of the face seen at St. Saviour's Union Infirmary, East Dulwich Grove. The erythema in every case spread symmetrically over the nose and both cheeks, generally, however, being rather more extensive on one side than the other. All the patients were suffering from some affection of the stomach or intestines, and extremely ill at the time of appearance of the rash. One was a feeble old woman suffering from diarrhoea and vomiting. Two were the subjects of acute phthisis complicated by diarrhoea, and a fourth, a case of hæmatemesis from cirrhosis of the liver.

CASE 1.—A woman aged seventy-seven was admitted to the infirmary on March 31st, 1891, with irregular heart, no bruits, no albumen in urine. On April 15th she had severe epistaxis from which she never thoroughly recovered. For the next six weeks she had attacks of vomiting and diarrhoea, alternating with constipation. On May 30th, after two or three days of vomiting and diarrhoea, an erythema appeared on the face with rise of temperature to 102° F. The erythema had the distribution of lupus erythematosus, affecting the nose and both cheeks but descending slightly lower on the left than on the right. The affected skin was slightly swollen, of pinkish red colour with well defined edge. The eyelids were reddened and somewhat oedematous. The temperature

rose to 104° on the second day after which it remained between 100 and 102° until death occurred on the fifth day. The reddened area had then spread downwards on to the neck on either side, uniting under the chin, leaving that as a white island. It had also spread halfway up the forehead. Slight desquamation was commencing on the right side of the nose. The diarrhoea and vomiting had ceased when the rash appeared and the bowels were constipated during the last five days.

CASE 2.—A woman aged thirty was admitted on Feb. 3rd, 1892, with signs of extensive recent phthisis following old disease at the left apex. She suffered from diarrhoea and had five or six small deep ulcers on the upper surface of the tongue. On Feb. 14th, the day of death, there was swelling and redness of the nose and both cheeks. The reddened area had a well defined edge, was slightly tender but there was no complaint of itching or pain. The nurse said that it had commenced four hours previously.

CASE 3.—A man aged thirty-five was admitted on Jan. 29th, 1891, with signs of extensive phthisis and a history of only a few weeks' illness. He had severe diarrhoea. On Feb. 16th he had symmetrical redness and swelling of nose and both cheeks with well defined edge. The redness continued until death on the following day, but had not spread beyond the cheeks. He was conscious to the last,

but made no complaint of his face, his attention being directed to his cough.

CASE 4.—A man aged fifty-three was admitted to the infirmary on June 3rd, 1891, suffering from jaundice with ascites, due to cirrhosis of the liver. On July 6th he had severe hæmatemesis, vomiting about two pints of blood. The hæmorrhage nearly proved fatal. On the following day an erythema of precisely the same character as that seen in the other three cases appeared on the nose and cheeks. The temperature was 100.2°. This disappeared in four or five days, as the patient slowly recovered from the loss of blood.

In one of the above cases the swelling is described as slight—that is to say that it was slight compared with the swelling usually seen in erysipelas of the face, in all, however, it was sufficient to cause considerable disfigurement. Its distribution associates it with one variety of Guitta Rosea, of which I suppose it may be considered a very acute form. It is possible that the first case may have been erysipelas, but at its commencement it closely resembled the other three, in which there could be no suspicion of that disease. In that case and in the other two that ended fatally the erythema may have been merely a symptom of failure of some part of the vaso-motor system, the prelude to general circulatory failure. In the fourth case the patient was almost moribund from severe hæmorrhage at the time of the appearance of the rash and it disappeared as he recovered. The high temperature noticed in the old woman, which was uncomplicated by the pyrexia of acute disease, may be considered to militate against this view, but not unfrequently especially in cases of diarrhoea, the temperature rises as the final collapse approaches. This has invariably been the case in my small experience of children in one instance the temperature reaching as high as 108° F. before death.

Greenwich, S. E.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL

A CASE OF RUPTURE OF THE LIGAMENTUM PATELLÆ, WITH TREATMENT

By CLEMENTS HAILES, M.D., C.M. EDIN.,
ASSISTANT SURGEON TO THE BRISTOL EYE HOSPITAL.

THE comparative rarity of rupture of the ligamentum patellæ makes the record of any such case of considerable interest, especially when the treatment adopted has resulted in a perfectly satisfactory recovery of the injured parts, as in the following case.

H. B.—, whilst leaving his hotel missed a step and fell heavily, his knee giving way he found he was unable to rise. In this condition he was found, and a medical man was sent for, who had his leg temporarily fixed on a splint and ordered his removal to bed. On the following day I was telegraphed for, and saw him with Mr. Alford of Weston super-Mare, the gentleman who had attended him. The following conditions were found. The patella on the injured side was drawn upwards on the thigh three-quarters of an inch and a deep depression was left at the usual site of the ligamentum patellæ. The distance between the lower border of the patella and the upper border of the tuberosity of the tibia on the injured side was one inch and three-quarters, whilst on the sound side measurement gave one inch. As the chief point in treatment was to counteract the pulling upwards of the patella by the extensor cruris muscles I had a splint made after Manning's pattern, a description of which with the woodcut is given in "Erichsen's Science and Art of Surgery." It consists of a back splint hollowed to fit the shape of the back of the leg and reaching from the gluteal fold to the sole of the foot, with a footpiece attached at a right angle. Where the heel comes it is deeply hollowed, and about nine inches above is an obliquely punched slit across the splint about two inches and a half long. A bar runs through the hollow at the heel of the splint and projects on either side. The limb having been bandaged to the knee, strips of plaster cut two inches wide and long enough to overlap in front of the thigh are stitched by their centres to a strip of stout calico or webbing and applied to the thigh from above down-

the Medical Society's Transactions, asks, "Should the iodide of potassium be used in association with Iufnell's treatment?" In the debate which followed the iodide was by the majority of speakers regarded as an adjunct of great value. Dr Broadbent expressed the opinion that it strikingly promotes coagulation within the sac. As to the question of the diagnosis in these cases in the first it was unfortunately verified post mortem and the specimen showing the large coagulum is now in the museum of the Seamen's Hospital. In the second case the combination of pulsating tumour, loud systolic bruit and diastolic shock left no room for doubt. The situations of the aneurysms were most unfavourable and they consequently afford ground for encouragement even in the gravest cases.

ON AUSCULTATORY PERCUSSION OF THE SKULL, AND THE STATE OF THE SCALP IN CHRONIC HYDROCEPHALUS AND OTHER MORBID INTRA CRANIAL CONDITIONS.

BY ALEX. ROBERTSON, M.D., F.F.P.S.G.,
PROFESSOR OF MEDICINE, ST MUNGOS COLLEGE AND PHYSICIAN TO THE ROYAL INFIRMARY, GLASGOW.

VIBRATIONS are readily conducted from one part of the skull to another, thus, on listening with the stethoscope on the side of the head over the upper part of the coronal suture while the soft tips of the fingers tap smartly the opposite side of the cranial summit, the sound of the taps is heard very distinctly. However, the note in the young and in mature life differs considerably. With a view to determine the effect of age in modifying the sound I lately examined fifty individuals thirty of whom were children under twelve and twenty adults. In the child the sound is more hollow and the resonance greater than in the adult, and this is even more striking in the infant. The conduction of the vibrations is most free across the summit of the head about its middle. It is less obvious if while listening on one side, percussion is made on or around either the opposite parietal or frontal eminence, especially the latter. When the skull undergoes change through disease the normal sound, both in adults and children is altered. Definite observation on the alteration of note appears hitherto to have been made only in connection with chronic hydrocephalus. My attention was first called to it about three years ago by Professor Macewen of Glasgow, in a case of this disease, and he also pointed out its presence in two or three similar cases in the Sick Children's Hospital soon afterwards. Since then, with the exception of one or two casual observations, there seems to have been little further study of the subject. Two patients suffering from hydrocephalus having recently come under my care in the infirmary I have taken advantage of the opportunity to investigate the nature and probable causation of the sound in question. The condition of the scalp was also carefully observed and I think presents points of practical importance. These cases will now be briefly recorded.¹

CASE 1.—A domestic servant, aged fifteen years and a half, was admitted into the infirmary on Oct. 13th, 1892. Her parents stated that she was considered clever when at school and that she was in good health till May, 1890. She was then sent to learn dressmaking, but at the end of a year her employer complained of her slowness and general incapacity. Shortly afterwards, following on a sudden attack of sickness and vomiting, the power of the right leg was found to be impaired, and ever since, though able to walk, there has been weakness of that extremity with a degree of stiffness of gait. On several occasions she has wetted her clothes during the day as well as at night. She has not yet menstruated. In other respects both personal and family history are satisfactory.

On admission there was obvious simplicity and childishness in her manner and bearing though replies to simple questions were correct. The head was distinctly larger than usual at the girl's age and also very flat on the top. This increase in size had likewise been noticed by her relatives. The scalp particularly over its middle, was soft and relaxed to the touch, and was also generally more movable than usual. Auscultatory percussion of the head at the points mentioned

and in the way described revealed undue resonance, and the note partook somewhat, though not markedly, of the cracked pot character. There was no tenderness on percussion of the skull with the finger at any part. The functions of the cranial nerves were normal. The grasp of both hands was weak, but the dynamometer showed no difference between them. Muscular sense was impaired. Sensation was good. Reflexes at the elbow and wrist were a little exaggerated. The knee reflexes were also increased and there was slight ankle clonus.

Since admission she has not improved. She has not complained much of headache, but has had giddiness and sudden vomiting once or twice a week. There are indications of a slight and receding neuro-retinitis in the fundus of both eyes. Since the application of two fly blisters over the head the relaxation of the scalp has become less obvious, but it is still present. The measurements of the head on Nov. 12th were: From root of nose to occipital protuberance, 13½ in., across, from ear to ear, 12½ in., circumference at one inch above ears, 23 in. Unfortunately the head was not measured on admission. The diagnosis was: Small tumour, probably pressing on the straight sinus and so causing serous effusion into the lateral ventricle.

CASE 2.—A boy, aged four years, admitted July 30th, 1892. This child is stated to have been healthy till it was two years old. Then he had abdominal troubles, from which, however, he recovered. His head had been enlarging unduly during this last year and he had complained much of headache at intervals. In June he had an unconscious attack, followed by general rigidity of arms and legs, which continued for about one and a half hours. For many months he has been unable to walk and during the same time he has had no power over the bladder and rectum. The little patient has the characteristic aspect of hydrocephalus. The head is very heavy and flat on the top. The anterior fontanelle is prominent and distinct fluctuation is to be felt in it and along the lines of the adjoining sutures. The scalp is very thin and stretched and fits very close to the skull. Auscultatory percussion brings out a hollow, drum like note, with less approach to the cracked pot character than in the other patient. The measurements of the head taken on Aug. 3rd were: Antero-posterior, 13½ in., from ear to ear, 13½ in., circumference, 21½ in. On Nov. 12th, in the same order, they were respectively, 14, 14, 21½.

With respect to the softening and relaxation of the scalp in Case 1 the condition seems analogous to that of the vulva, vagina and os uteri at the beginning of parturition, though less marked than in them. It is to be observed that the changes in these parts are not to be regarded as wholly due to mere mechanical distension, but are to be attributed largely to the provision of nature which prepares them for the process of stretching at a later stage. So, too, it may be with hydrocephalus. At the commencement of the distension resulting from a comparatively small effusion, and probably also till the amount be considerable, the scalp may be in this state of relaxation, but later, especially when the fontanelles are open and the bones are separating at the sutures, it will become thin and stretched, corresponding with the state of the os uteri as labour advances. Respecting the mode of production of the altered note heard by the method of auscultatory percussion in such cases it is probably due to the thinning and stretching of the skull and membrane covering the fontanelle in children where the latter is still open. On the other hand in cases such as that of the girl, where the note partakes of the cracked pot character, the commencing separation of the bones at the sutures and consequent impaired continuity of the skull will contribute to the effect. These conditions exist in hydrocephalus, but atrophy of the cranial bones, however induced, will probably be attended by a degree of the same note, just as it is present in the thin skull of the healthy child.

Auscultatory percussion may prove of use in other conditions which probably modify the conduction of vibrations along the bones—for example, superficial hæmorrhages and new formations in the bone, membranes and cortex. These, if considerable, may be likely to interfere with the transmission of vibrations. But a diminution in the normal note produced by tapping the skull would also be valuable as a physical sign if it proved to be indicative of certain morbid changes at the part under examination. Thus a subdural effusion of blood consequent on injury or apoplectic seizure, may modify the note by its pressure on the overlying bone, and if so the alteration of sound would be a guide to the point at which the operation of trephining the skull should be performed for the purpose of removing the effused blood.

¹ The patients were shown and these points demonstrated at a meeting of the Glasgow Clinical and Pathological Society on Nov. 14th, 1892.

primary union, but the bronchitis gave us much alarm and threatened more than once to carry off the patient before she could be allowed to get up, otherwise she made an excellent recovery, and although not wearing a truss the hernia did not again come down during the remainder of her life, which was terminated by the bronchitis three months after the operation. Although her age was so great she was thin and wiry, and had she not been a sufferer from bronchitis would no doubt have survived for several years. From the matted and adherent state of the omentum the hernia must have existed some considerable period of time before it was noticed.

Chetwynd road, Highgate N W

THE TREATMENT OF OXYURIS VERMICULARIS

By B. H. NICHOLSON, M.B., C.M. EDIN.,
LATE RESIDENT SURGEON, ESSEX AND COLCHESTER HOSPITAL.

THREADWORMS are one of the commonest and yet one of the most troublesome ailments we are brought into contact with in practice and unless treatment is firmly and properly carried out, relapses are certain every few months, often producing reflexly epilepsy, chorea, convulsions, insomnia and many other debilitating and distressing troubles. First, one or two remarks as to the habitat of the nematode. The ova may develop in the large intestine of the host, or after irritation and scratching of the anus the ova may be carried to the mouth of the patient, swallowed and then the embryo may be liberated from its cell wall by the action of the gastric juice and then gradually become a mature oxyuris and inhabit the cæcum and large intestine. By the time the female oxyuris reaches the sigmoid flexure and rectum the uterus is full of ova which may be born into the intestinal tract or liberated on the expulsion of the oxyuris from the anus.

Treatment—The child should be bathed twice daily, the underclothing changed frequently, a draw sheet put below the patient at night, the nails kept short, the fingers dipped frequently in an infusion of quassia, and the anus smeared night and morning with an ointment composed of nitrate of mercury with a small quantity of extract of quassia added. The condition of the bowels should be attended to. Mercury with chalk and rhubarb and soda powder should be prescribed to secure daily evacuation. Now santonin must be given every other night for a week and if taken longer santoninism must be guarded against—viz. tenesmus, spasms, yellow vision, hemorrhages and red yellowish urine. Attention should be paid to the bile secretion, the great antiseptic of the intestinal tract. The endeavour should be to increase peristalsis and diminish the secretion of mucus by giving as a tonic citrate of iron and strychnine in moderate doses after food. I have lately been using with great benefit extract of quassia made into a suppository with cacao butter (one to three grains), these suppositories are easily introduced at night and children do not object to them. Injections are disliked by children and it is difficult to get the mother or nurses to take the necessary trouble. An injection of menthol (one grain) dissolved in one ounce of olive oil is often useful. The child should have abundance of out-door exercise and a free diet, avoiding uncooked vegetables, fruit, sweets &c and anything likely to produce catarrh or increase the mucus. The patient should be isolated during the period the oxyurides are being expelled, kept from school, should sleep alone and not be allowed to mingle with other children. This treatment should be maintained until all signs of oxyurides are obliterated.

Colchester

SPORTS IN AID OF THE LONDON HOSPITALS—A meeting was held on Dec 30th, at the offices of the Hospital Saturday Fund in Farringdon road, in furtherance of the proposed athletic and cycling sports in aid of the hospitals of the metropolis. The chief business was the election of a council, from which a practicable committee will be chosen to carry out the idea.

FATAL FOOTBALL CASUALTY—On the 3rd inst an inquest was held at Durham on the body of a football player who suffered fatal injuries in a match played in October last. It appeared that the injury was sustained by the deceased coming into violent collision with another player, causing fracture of the spine.

HOSPITAL PRACTICE, BRITISH AND FOREIGN

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed et Caus. Morb.*, lib. iv. Proœmium.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO BRIDGE ROAD

CONGENITAL CYSTIC HYGROMA OF NECK TREATED BY
DISSECTION AND IODINE.

(Under the care of Mr MARMADUKE SHEILD.)

THIS case is a very typical one of those congenital cervical cysts to which the names "cystic hygroma" and "hydrocele of neck" have been applied. The affection has been fully described in this country among others by Mr T. Smith, Mr Birkett and Mr Holmes. This case forcibly illustrates, what was especially pointed out by Mr Holmes, that, however superficial they may appear, the major part of these cystic growths invariably extends beneath the deep fascia, the superficial cysts being merely hernial protrusions which have likely enough found their way through the deep fascia by pressure. The free extension of this cyst by large loculi beneath the deep fascia, reaching towards the base of the skull and hyoid bone, is worthy of attention in relation to the theory propounded by Mr Sutton, that these cysts may be representative of the laryngeal sacculculi of certain monkeys. The amount of soft, vascular, intra-cystic growth in this case was remarkable, and when fungation occurred from inflammation caused by the iodine it was indeed difficult to believe that the growth was not of a malignant nature. As is well known, all kinds of treatment have been employed to effect the cure of these cysts. All treatment is risky, for young children ill bear extensive operations and prolonged suppuration. Probably it would be well in the majority to postpone any operative interference until the child has attained the age of puberty, but inflammation of the cysts may compel us to interfere, and so may the importunities of relatives. If the surgeon be well assured that even in the most simple looking cases he has really a difficult task before him, removal of these growths by dissection is probably the most satisfactory treatment. The superficial cysts can thus be safely removed and the deeper loculi obliterated by drainage and the subsequent inflammatory process. The masses of solid growth, unless easily removed, had better be left intact. They are often very vascular and so incorporated with adjacent structures that safe removal may be out of the question. The perilous illness through which a young patient operated upon for congenital cervical cyst may have to pass is illustrated by the present case. Indeed, had it not been for the care bestowed upon the case by the house surgeon, Mr Richards, and the employment of excellent nursing, a different result might have occurred. In conclusion it may be borne in mind that quite a significant number of these cases undergo spontaneous cure by inflammation, suppuration and subsequent shrinkage. This is especially likely to occur when the cyst is of enormous size and liable to injury. Hemorrhage has also taken place into the cyst cavities with subsequent shrinkage, and the possible communication or close connexion of the cysts with large veins in the neck must not be lost sight of in performing the operation of removal by dissection. For the notes of the case we are indebted to Dr Theodore Fisher, registrar to the hospital.

F B—, aged one year and seven months was admitted on Sept. 12th 1892. History. A swelling in the hinder part of the neck, present at birth, but is said to have been much smaller at that time. Has twice been tapped by Dr Daniel of Epsom, who sent the case to Mr Sheild, the last tapping having been six weeks ago. Clear fluid was drawn off. The swelling has increased considerably in the last six months.

On admission to hospital the child was fairly well-nourished, but pale and delicate looking and of stunted

wards, thus grasping the muscles so that when traction is made on the calico band the muscles with the patella are drawn downwards. This band is passed through the slit in the splint and a loop is made in it at that level, through which a bar similar to the one in the hollowed heel is passed, and then by stronger or weaker elastic bands, attached round the ends of the bars, greater or less traction on the muscles inserted into the patella can be made. The patient returned home by rail after this splint had been fitted some days and wore it for six weeks after which the knee was put up in plaster of Paris for a fortnight. Passive motion and massage were then practised, the stiffness gradually wearing off, he being able in a week or two, wearing one of Dr Fisher's flexible knee caps, to walk about with the aid of a stick. Now at an interval of three years and a half he is able to use the leg freely, and says he has to think before he can remember which was the injured leg, the muscles having a firm point of fixation in the new tissue. The measurement between the lower border of the patella and the upper border of the tuberosity of the tibia is now one inch. The patient is subject to chronic albuminuria but this has not affected the process of repair.

MUMMIFICATION OF A FÆTUS IN THE UTERUS

By JAMES OLIVER, M.D. & R.S. EDIN.

A WOMAN aged twenty six and married eight years has had four children but no miscarriage. The last child was born twenty seven months ago and was suckled for two years. After this confinement the menstrual discharge reappeared when the child was fifteen months old and it recurred regularly every month until March 24th. From this date until Aug 15th there was complete amenorrhœa. On Aug 15th she complained of pain in the lower abdomen and simultaneously she noted the existence of a slight hæmorrhagic discharge from the vagina. The pain, which was never severe and the hæmorrhage, which was slight, continued for seven days. Between Aug 22nd and Sept. 21st—the date on which the patient came under my observation—nothing worthy of note had occurred. On Sept 21st the physical signs were as follows. Nothing was revealed by abdominal examination. Vaginally the cervix which was not soft, was directed towards the left side of the pelvis. In front of the cervix and on the right side was felt a somewhat lobulated swelling about the size of a small cocoa nut, this swelling was the body of the uterus. As I considered the history and physical signs to be in keeping with the existence of a mummified fœtus in the uterus the patient was admitted into hospital. On Oct 21st patient again began to complain of pain and simultaneously there was observed a free discharge of blood from the vagina. On the following day an almost round mass was expelled. The longitudinal diameter of this mass was three inches and the transverse two inches and a half. The greater part of the mass was placental it was lobulated and fibrous looking. Through a thinned portion of the mass the fœtus enclosed in its own membrane was expelled. The cavity in which the fœtus had lain was lined by another distinct membrane.

Description of the fœtus—It is five inches long and the head is disproportionately large. The eyelids are open, but no part of the eyeball can be distinguished. No definite hairs can be made out on the scalp. The mouth is large and open and the tongue protrudes slightly. The fingers and toes are distinct, but the presence of nails is doubtful. The umbilicus is at the lower end of the middle third of the linea alba. There is no remnant of the cord. The labia majora are distinct and the clitoris is comparatively large.

It is more than probable that this patient conceived soon after March 24th that death of the fœtus occurred on or about Aug 15th, and that the process of mummification extended from this date until Oct 22nd the date on which the contents of the uterus were expelled.

TWO CASES OF STRANGULATED FEMORAL HERNIA WITH RECOVERY AFTER OPERATION

By CHESMAN BARKER, M.B., L.R.C.P. LOND., M.R.C.S.

THE following cases may be of interest to the readers of THE LANCET as showing the success which follows early treatment of strangulated femoral hernia by operation, even

though performed by surgeons unskilled in herniotomy, and without the manifest advantages pertaining to operations performed in hospital. That a femoral hernia when strangulated is a very much more serious affair than an inguinal hernia in the same condition is well known, but the comparative mortality is perhaps not appreciated at its proper ratio by the profession generally. The statistics of St. Bartholomew's Hospital for the year 1891, collected by Messrs. Bowlby and Lockwood, show that thirty one operations for strangulated hernia were performed in that year, and that of these six were for inguinal and twenty five were for femoral hernia. Of the inguinal cases none died, giving for that year a mortality of 0 per cent. Of the femoral cases eleven died, giving a mortality of 44 per cent. It is probable that this greatly increased mortality is largely due to the fact that the intestine is damaged so rapidly in femoral hernia by the unyielding margins of the ring that the delay which generally takes place in conveying a patient to a hospital is sufficient to allow the intestine to be injured beyond recovery. That femoral hernia is not more dangerous than the inguinal variety, if operated upon in time, is probable, and in support of this statement I give below two cases of femoral hernia in which operation within two hours of recognising the condition was followed by rapid recovery. In both cases the intestine was quite uninjured, being only a little congested, and it is highly probable that if time had been wasted in sending these patients to a hospital, or if one had had to send many miles for a surgeon, the intestine would have fallen into a condition rendering the operation one of difficulty and danger instead of the easy and successful measure it proved to be.

CASE 1.—On March 31st, 1892, I was called to see Mrs. H. W., aged thirty years whom I found to be suffering from a strangulated right femoral hernia. The hernia had existed for several years, but she had never worn any truss. She had been in the habit of putting it back herself, but on March 28th it became painful and she was unable to reduce it. Next morning she was in considerable pain and was vomiting and the bowels had not been moved. On the following day when I saw her she was in great pain and her tongue was dry and furred, and her expression was anxious. The hernia was tense and tender, was irreducible and had no impulse on cough. I therefore at once decided to operate, and the patient being put under the A.C.E. mixture, a vertical incision was made over the swelling, and the sac being opened on a director showed that the contents consisted chiefly of omentum. A small incision of Gimbernat's ligament easily allowed of the reduction of the intestine, the omentum being firmly adherent along the outer side of the femoral canal was ligatured and cut off, as also the redundant portion of the sac after the neck had been sewn up with silk ligatures, the skin wound was united with silk sutures and an indiarubber drainage tube inserted, the wound was dressed with boracic acid lint and absorbent wool, and fifteen minims of tincture of opium were ordered every four hours. On the second day after the operation her temperature rose to 99.2, and this was its highest point during her illness, the wound healed in nearly its whole length by first intention, but a little suppuration at its lower corner delayed complete union until the end of a fortnight, the bowels were spontaneously opened at the end of nine days, and four weeks after the operation she was able to wear a truss and get about her daily work. I saw her a few weeks ago and then she was in perfect health and the hernia had not again come down.

CASE 2.—On April 26th 1892 I was asked to see Mrs. B.—aged seventy three years, Dr. Owen Roberts, her medical attendant, having discovered the presence of a strangulated hernia. She only noticed the lump a fortnight ago, and on the 25th was seized with pain and vomiting, the bowels being constipated. In the right groin below Poupart's ligament was a small tense swelling, in which on coughing no impulse could be detected, and feeling as though it contained much fluid. The patient was also suffering from an almost continuous cough, the result of chronic bronchitis. Dr. Roberts having put the patient under the A.C.E. mixture taxis was tried, but the hernia not showing any tendency to go back I proceeded to operate and found as I had suspected, that the sac contained much fluid. It contained omentum firmly adherent to the sac and a small knuckle of intestine of a deep claret color. The subsequent steps of the operation were similar to those in the preceding case, the omentum being ligatured with silk ligatures and the neck of the sac sewn up with the same. Seven days after the operation the wound had healed by

primary union, but the bronchitis gave us much alarm and threatened more than once to carry off the patient before she could be allowed to get up, otherwise she made an excellent recovery, and although not wearing a truss the hernia did not again come down during the remainder of her life, which was terminated by the bronchitis three months after the operation. Although her age was so great she was thin and wiry, and had she not been a sufferer from bronchitis would no doubt have survived for several years. From the matted and adherent state of the omentum the hernia must have existed some considerable period of time before it was noticed.

THE TREATMENT OF OXYURIS VERMICULARIS

By B. H. NICHOLSON, M.B., C.M. EDIN.,
LATE RESIDENT SURGEON ESSEX AND COLCHESTER HOSPITAL.

THREADWORMS are one of the commonest and yet one of the most troublesome ailments we are brought into contact with in practice and unless treatment is firmly and properly carried out, relapses are certain every few months, often producing reflexly epilepsy, chorea, convulsions, insomnia and many other debilitating and distressing troubles. First, one or two remarks as to the habitat of the nematode. The ova may develop in the large intestine of the host or after irritation and scratching of the anus the ova may be carried to the mouth of the patient, swallowed and then the embryo may be liberated from its cell wall by the action of the gastric juice and then gradually become a mature oxyuris and inhabit the cæcum and large intestine. By the time the female oxyuris reaches the sigmoid flexure and rectum the uterus is full of ova which may be born into the intestinal tract or liberated on the expulsion of the oxyuris from the anus.

Treatment—The child should be bathed twice daily the underclothing changed frequently, a draw sheet put below the patient at night the nails kept short the fingers dipped frequently in an infusion of quassia, and the anus smeared night and morning with an ointment composed of nitrate of mercury with a small quantity of extract of quassia added. The condition of the bowels should be attended to. Mercury with chalk and rhubarb and soda powder should be prescribed to secure daily evacuation. Now santonin must be given every other night for a week and if taken longer santoninism must be guarded against—viz. tenesmus, spasms, yellow vision, hæmorrhages and red yellowish urine. Attention should be paid to the bile secretion, the great antiseptic of the intestinal tract. The endeavour should be to increase peristalsis and diminish the secretion of mucus by giving as a tonic citrate of iron and strychnine in moderate doses after food. I have lately been using with great benefit extract of quassia made into a suppository with cacao butter (one to three grains), these suppositories are easily introduced at night and children do not object to them. Injections are disliked by children and it is difficult to get the mother or nurses to take the necessary trouble. An injection of menthol (one grain) dissolved in one ounce of olive oil is often useful. The child should have abundance of out-door exercise and a free diet, avoiding uncooked vegetables, fruit, sweets &c. and anything likely to produce catarrh or increase the mucus. The patient should be isolated during the period the oxyurides are being expelled, kept from school, should sleep alone and not be allowed to mingle with other children. This treatment should be maintained until all signs of oxyurides are obliterated.

Colchester

SPORTS IN AID OF THE LONDON HOSPITALS—

A meeting was held on Dec. 30th, at the offices of the Hospital Saturday Fund in Farringdon road, in furtherance of the proposed athletic and cycling sports in aid of the hospitals of the metropolis. The chief business was the election of a council, from which a practicable committee will be chosen to carry out the idea.

FATAL FOOTBALL CASUALTY—On the 3rd inst an inquest was held at Durham on the body of a football player who suffered fatal injuries in a match played in October last. It appeared that the injury was sustained by the deceased coming into violent collision with another player causing fracture of the spine.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO BRIDGE ROAD

CONGENITAL CYSTIC HYGROMA OF NECK TREATED BY
DISECTION AND IODINE.

(Under the care of Mr. MARMADUKE SHEILD.)

THIS case is a very typical one of those congenital cervical cysts to which the names "cystic hygroma" and "hydrocele of neck" have been applied. The affection has been fully described in this country among others by Mr. T. Smith, Mr. Burckett and Mr. Holmes. This case forcibly illustrates what was especially pointed out by Mr. Holmes that, however superficial they may appear, the major part of these cystic growths invariably extends beneath the deep fascia, the superficial cysts being merely hernial protrusions which have likely enough found their way through the deep fascia by pressure. The free extension of this cyst by large loculi beneath the deep fascia, reaching towards the base of the skull and hyoid bone, is worthy of attention in relation to the theory propounded by Mr. Sutton, that these cysts may be representative of the larvæal sacculi of certain monkeys. The amount of soft, vascular intra-cystic growth in this case was remarkable, and when fungation occurred from inflammation caused by the iodine it was indeed difficult to believe that the growth was not of a malignant nature. As is well known all kinds of treatment have been employed to effect the cure of these cysts. All treatment is risky, for young children ill bear extensive operations and prolonged suppuration. Probably it would be well in the majority to postpone any operative interference until the child has attained the age of puberty, but inflammation of the cysts may compel us to interfere, and so may the importunities of relatives. If the surgeon be well assured that even in the most simple-looking cases he has really a difficult task before him, removal of these growths by dissection is probably the most satisfactory treatment. The superficial cysts can thus be safely removed and the deeper loculi obliterated by drainage and the subsequent inflammatory process. The masses of solid growth, unless easily removed, had better be left intact. They are often very vascular and so incorporated with adjacent structures that safe removal may be out of the question. The perilous illness through which a young patient operated upon for congenital cervical cyst may have to pass is illustrated by the present case. Indeed, had it not been for the care bestowed upon the case by the house surgeon, Mr. Richards and the employment of excellent nursing, a different result might have occurred. In conclusion, it may be borne in mind that quite a significant number of these cases undergo spontaneous cure by inflammation, suppuration and subsequent shrinkage. This is especially likely to occur when the cysts are of enormous size and liable to injury. Hæmorrhage has also taken place into the cyst cavities with sub-sequent shrinkage, and the possible communication or close connexion of the cysts with large veins in the neck must not be lost sight of in performing the operation of removal by dissection. For the notes of the case we are indebted to Dr. Theodore Fisher registrar to the hospital.

F. B.—aged one year and seven months was admitted on Sept. 12th, 1892. History. A swelling in the lower part of the neck present at birth but is said to have been much smaller at that time. Has twice been tapped by Dr. Daniel of Epsom, who sent the case to Mr. Sheild, the last tapping having been six weeks ago. Clear fluid was drawn off. The swelling has increased considerably in the last six months.

On admission to hospital the child was fairly well-nourished, but pale and delicate looking and excited.

growth, rickety, well marked large Parrot's nodes, slight bending of ribs and enlargement of wrists. There was an ovoid, strikingly translucent, soft, cystic swelling, the size of a hen's egg, situated in the right posterior cervical triangle. It just overlapped the mastoid process above and extended downwards to the clavicle. Within the cyst was a hard, slightly nodular mass the size of a marble, apparently attached to the sterno-mastoid muscle. The skin over the swelling was smooth and natural in colour, and could easily be separated from the wall of the cyst.

On Sept. 14th, the A.C.E. mixture having been administered, Mr. Sheild made an incision over the swelling about three inches long, parallel to the posterior border of the sterno-mastoid. The skin was dissected off the very thin cyst wall as far as the surface of the muscles on both sides. The cyst was at this stage unavoidably opened and found to pass by a narrow opening through the deep fascia, under the sterno-mastoid, upwards towards the hyoid bone, downwards towards the sternum. There were several smaller cysts and some solid growth, and all these deeper parts were intimately connected with the carotid sheath. On opening the cyst three or four ounces of clear lymphoid fluid escaped, which feebly coagulated. The portion of cyst wall from which the skin had been dissected off was removed and several of the smaller cysts opened, the large prolongation beneath the sterno-mastoid was washed out with equal parts of tincture of iodine and water. Finally the skin was sewn

to the edges of the cyst and the large cavity was plugged with iodoform gauze.

Sept. 20th.—Temperature rose to 103° last night, till then there has been little rise since the operation, the highest has been 100·6°. The child's cheeks are flushed. Pulse 144, occasionally drops a beat. The wound is filling up well with granulations.

Oct. 17th.—Temperature remained between 100° and 103·8° until Oct. 2nd, when it fell to normal. From then till yesterday the child seemed to be steadily improving, when the temperature suddenly rose to 104·8°. To-day a director was passed into the wound in several directions but no pent up pus was discovered. The cavity has granulated up well, but a fungating mass the size of a russet apple remains, presenting much the appearance of sarcoma.

19th.—For some time a small cyst has been noticed between the anterior border of the sterno-mastoid and the angle of the jaw, and during the last two or three days another smaller one lower down and rather more superficial has been observed. A.C.E. mixture was given. A small skin incision was made and the cyst opened by pushing in a steel director. About a teaspoonful of clear fluid was evacuated. The temperature remains between 100° and 103°.

24th.—There is some oedema and a slight redness over the cyst area and there are a few dilated veins running upwards from the upper part of the right side of the chest over the

clavicle. Several small incisions were made by the house surgeon and warm boracic acid dressings applied.

25th.—There are some signs of broncho-pneumonia at the right base. The temperature oscillates between 102° and 103°, respirations 42, pulse 160. The child is evidently very ill, but takes nourishment well.

Nov. 6th.—The temperature down to normal to-day, the signs of broncho-pneumonia have disappeared. The redness and oedema round the wound have also disappeared. There are still some distended veins running up over the clavicle.

18th.—The temperature has remained normal since the last note. The wound is quite healed. There is a thin linear scar about one inch long by a quarter of an inch, parallel with and just behind the middle of the posterior border of the sterno-mastoid muscle, to which it is attached by a mass of indurated tissue about the size of a hazel nut. The skin around the scar is puckered into numerous folds. In front, between the angle of the jaw and the sterno-mastoid muscle, a small soft cyst can be felt about the size of a haricot bean. The enlarged superficial veins running up over the clavicle have diminished in size. A complete cure seems established of the main bulk of the tumour, but the child is pale and puny and is seriously pulled down by its severe illness.

EVELINA HOSPITAL FOR SICK CHILDREN.

CASES OF FACIAL PARALYSIS OF RHEUMATIC ORIGIN IN CHILDREN, IMPLICATION OF THE SOFT PALATE.

(Under the care of Dr. GEORGE CARPENTER.)

FACIAL PARALYSIS in infants and children is common enough if those cases associated with middle-ear disease and otorrhoea with caries of the petrous portion of the temporal bone be taken into consideration. Much less frequently abscess or enlarged glands behind the angle of the jaw or parotid implication will cause this condition. Congenital syphilis (very rarely), traumatism from delivery with forceps, disparity of foetal and maternal parts, and prolonged, though normal labour, may form causal agents. There is also a functional form, one secondary to post-pharyngeal abscess (Bokdy) and an incurable congenital form (Henoch) that have been reported. Paralysis such as is met with in adults from exposure and due to neuritis of the nerve in the Fallopiian canal is thought by many observers to be rare in childhood. Goodhart has seen it only once in a girl of about eight years, but Steiner and Henoch, as also Angel Money, mention cases of this nature. Gowers, on the contrary, considers the affection rare under ten and remarks "only two cases occurred in this period, and each was in the second year of life."

The following account of cases under the care of Dr. George Carpenter may therefore prove of interest, they are brought forward not only on this account, but because one of them had the soft palate markedly affected. This happened to Case 2 in the list.

CASE 1.—A child aged five years was brought to the hospital on Sept. 17th, 1891, for weakness of the eye and deafness. She had right-sided facial paralysis. This came on quite suddenly and persisted for two months and a half. There was no discharge from the ear and there never had been. The short process in the right ear appeared prominent. There were no signs of an antecedent or present perforation. The left ear contained wax normally. The child said she could hear better with the right ear. This was probably due to paralysis of the stapedius and overaction of the tensor tympani.

CASE 2.—A girl aged nine years and a half had suffered from facial paralysis of the right side for eight months. She had been absent for three months since May 15th, 1890, with scarlet fever, at the New Cross Fever Hospital, but on her discharge returned under Dr. George Carpenter's care. She was last seen on Aug. 21st, 1890. Her state was as follows.—She could not frown on the affected side or close the right eye and the lower muscles on the same side of the face were quite paralysed. The tongue was straightly protruded. The mother stated she used to drag the right leg and did so a little when brought to the hospital and was weak in the right arm. Soft palate. At rest the uvula was nearer the left tonsil and moved towards the left on phonation. The movement was nearly all on the left side of the soft palate. The left tonsil was

enlarged, this was interesting because both tonsils were partially removed before her attack of scarlet fever. She spoke with a nasal intonation and liquid returned through the nose. There were no other palsies. The grasps were equal, reflexes normal, walking normal, no history of congenital syphilis, nor could the paralysis be accounted for in any way. The lesion must have been above the geniculate ganglion to cause the implication of the soft palate. There was nothing in the case to suggest syphilitic or new growth implication of the nerve or neighbouring nerves and it is probable that the neuritis extended up to the point mentioned. But such a bold statement is not by any means sufficient. Gowers¹ says "My own observations have led me to entertain considerable doubt as to the occurrence of paralysis of the palate from disease limited to the facial nerve in any part of its course." Only once in 100 cases had he found paralysis of the palate and this was on the side opposite to the palsy of the face. "The best established fact regarding paralysis of the palate is that it is produced by disease at the side of the medulla, damaging the hypoglossal and spinal accessory." Gowers is of opinion that it is very doubtful whether the petrosal branches of the facial nerve supply the palate and considers the spinal accessory responsible. Hughlings Jackson² also says that he has never seen paralysis of the palate due to disease of the facial nerve. Other writers, however, are of opinion that paralysis of the palate does occur in cases of facial paralysis sometimes. Any suggestion that might be made as to this being another instance of anatomical or physiological eccentricity of the palate can be met with the fact that fluids returned through the nose, showing unmistakably that there was paralysis. It was on the same side as the lesion and not on the opposite, as in Gowers' case. At no time was it possible to detect evidences of disease in other or neighbouring portions of the nervous system, and with the exception of the facial paralysis the child, as far as could be discovered, was perfectly well. She was seen by Dr Syers of the Great Northern Hospital and he quite concurred with the diagnosis which had been made. Until something occurs to negative this supposition the original diagnosis must hold good. Her name and the date when she was last seen have been given, so that should she have passed under the care of any other physician a sequel may be added. The child has left the address given and no further tidings of her can be obtained.

CASE 3.—A child aged seven years attended on April 13th, 1891. She had suffered from pain in the head and right ear for years. Her mouth was drawn to one side for a week. There was a neurotic history in the family in the shape of chorea, convulsions and epilepsy, and a great-aunt was in an asylum till she died. Three weeks back the child had an unusually severe "screaming fit" at night. She woke up screaming at midnight, did not know her mother and would not speak to her. She soon fell asleep, however. The next morning the girl was "puffy about the eyes." A week ago she complained of pain in the head and right ear and she was noticed to be deaf on the right side, the face was drawn to the left side. The child was thin-faced and pale, the right side of the face was expressionless, the right eye watery and the mouth drawn over towards the left side. When she frowned the left eyebrow alone moved. The right eye could not be closed, tongue protruded naturally, soft palate normal. Right ear. Tympanic membrane (?) marked by desquamating scales. She could not hear a watch held half an inch from the right ear. When the watch touched the mastoid process she could hear it. She had a discharge from the ear when quite young, nothing seen for two years—April 20th. Much about the same.—June 22nd. Face is much better.

CASE 4.—A boy aged two years and five months attended as Dr George Carpenter's out patient on Dec. 17th, 1891. On getting up a week prior to this he fell and could not stand up. He was quite well the night before, not subject to fits. There was never a discharge from the ears, no history of exposure to draught or cold. The following day something wrong was noticed with his face. The patellar reflexes were brisk. The arms were used equally and well. When the child laughed or cried the left angle of the mouth and the left orbicularis palpebrarum did not move. The eyeball did not roll up when an attempt was made to close the eye. The soft palate moved equally. The ears were full of wax, but otherwise normal. In three weeks time under galvanism he was almost well.

SEAMEN'S HOSPITAL, GREENWICH

ABSCESS OF LIVER WHICH RESULTED IN DEATH FROM SEPTICÆMIA.

(Under the care of Dr CURNOW.)

THIS case was an interesting one in many particulars, for (1) the rigors were so regular day by day that malarial fever was diagnosed and the plasmodium sought for until the failure of quinine and other anti malarial remedies led to a change in the diagnosis, for although septicæmia frequently simulates the rigors of an ague, yet this case shows this coincidence most strikingly, (2) the paroxysms of fever occurred daily for over fifty days and on one occasion a temperature of 108° was noted, (3) the abscess could not have been reached, even if its situation had been diagnosed, (4) the age of the abscess as shown by the thickness of its capsule and its fibrous character, but yet causing death by pyæmia, with secondary abscesses in both lungs as well as in the liver, and (5) the absence of any dysenteric mischief in the intestine. For the notes of this case we are indebted to Dr Spencer, house physician.

The patient, a German, aged thirty nine, was admitted into the Seamen's Hospital, Greenwich, on Oct 5th, complaining of daily shivering fits followed by sweating and fever. He had been a sailor for the greater part of his life, but had not lately visited any malarial countries. Eight years ago he was at Panama, but had no fever there and had never suffered from dysentery. Three months before admission, when at Boston, U.S., he was attacked with pain in the right side, which he attributed to a strain caused by lifting a heavy weight. He was laid up in hospital for five days, after which he recovered and seems to have kept in his usual health until two days after reaching England (Sept 30th), when he began to suffer with severe shivering fits every day, followed by fever and sweating and accompanied by severe headache. In the intervals between these attacks he expressed himself as feeling fairly well.

On admission (Oct. 5th) the patient was a well nourished man with a sallow complexion, there were no abnormal physical signs over the lungs or heart, the splenic dullness was enlarged and the edge of the spleen was just palpable, the liver could be felt about two inches below the costal margin in the nipple line and was a little tender on palpation, the tongue was much furred, the urine was free from albumen or bile pigment. Every day he was attacked with a violent rigor with a rise of temperature to 103° or 104°, followed by profuse sweating. The attacks came on generally in the evening and lasted from twenty minutes to a couple of hours. During these rigors he was in much distress, with rapid pulse and respiration vomited and complained of pains about the body. He was fairly comfortable, however in the intervals. Examination of the blood showed nothing abnormal, except some increase in the number of white corpuscles. He was treated first of all with quinine, to which in a few days arsenic was added. By Oct 21st the quinine was increased to fifteen grains every six hours. This treatment had no effect on the course of the disease. The rigors continued. The temperature rose higher than ever during the attacks reaching on one occasion 108°. A few days were passed without a rigor but occasionally two would occur on the same day, they occurred more frequently in the evening than at other times, but there was no marked periodicity in the times of their occurrence. By Oct 29th he had lost some flesh and had developed a cachectic appearance with sallow, earthy complexion, tincture of eucalyptus was ordered in three-grain doses and steadily increased without any influence on the disease.

After continuing much in the same condition for about three weeks he became markedly worse, pleuritic friction developed over the lungs in the infra axillary regions and in front of the chest on either side and coarse râles were heard over the lower part of both lungs, especially on the right side with some impairment of resonance. Some intermittent pain was complained of in the right shoulder and arm.

On Nov 25th Warburg's tincture was ordered. The temperature now became less oscillating although still very irregular. The respiration became continuously hurried and the strength failed rapidly. There was towards the close some cough, with thick mucopurulent sputum in small quantity. Death occurred somewhat suddenly on the morning of the 28th.

Autopsy, Nov 29th.—The liver was considerably en-

¹ Diseases of the Brain p 218.

² THE LANCET April 2nd 1887.

larged. In the posterior part of the right lobe, beneath the diaphragm, to which the organ was densely adherent, was an old abscess about as large as an orange. This abscess was surrounded by a dense whitish capsule and contained very thick, curdy pus, at its upper part was a small perforation through the diaphragm communicating with the right lung. In the neighbourhood and internal to it the liver substance was breaking down riddled with numerous small abscesses containing a thinner greenish pus. The right lung was adherent to the chest wall and bound down to the diaphragm by dense adhesions. The lower lobe was honeycombed with abscesses containing thick green pus, one of them as large as a pigeon's egg, several others rather smaller, there were also small scattered abscesses in the middle lobe and one near the apex of the upper lobe. The left lung was free from adhesions, the lower lobe contained several small abscesses near the surface and some fairly recent infarcts already breaking down in the centre, one of them about the size of a walnut. The left kidney was in a condition of hydronephrosis evidently of long standing, the upper part of the ureter being much dilated. The right kidney had undergone compensatory hypertrophy, but was healthy in structure. The bladder was small with a hypertrophied wall. No calculi were found. The spleen was enlarged and soft, but contained no abscesses and was free from infarction. There was some clear straw coloured fluid in the peritoneal cavity, but no signs of lymph. The intestine was perfectly healthy. The heart was natural in appearance, with the exception of slight thickening of the mitral valve.

LINCOLN COUNTY HOSPITAL

CASE OF SWALLOWING A RAZOR, GASTROTOMY, DEATH (Under the care of Mr W J CANT)

It would occupy too much of the space at our disposal to enumerate the various foreign substances which have been introduced into the stomach either by accident or by design, and we need mention only those which, from their character, consistence or shape, have necessitated removal by the operation of gastrotomy. The first recorded instance of the operation (which has been a very successful one) is that by Mathias of Brandenburg in 1602, who removed a knife nine inches in length from a man aged thirty nine. Beckhar of Dantzic in 1636 removed a knife from a peasant, which was afterwards preserved in the library at Königsberg. Dr A. C. Bernays removed a knife nine inches and a half long an hour after its ingestion. He refers in his paper to thirteen published accounts of the operation spread over a period of 251 years. Professor Lorota removed several needles from the stomach of a young woman. M. Pollajon removed a steel fork which had been swallowed by a juggler. A magnetic needle suspended by a cord proved useful in establishing the diagnosis. Dr M. D. Witte of Iowa removed a heavily plated four pronged spoon handled fork seven and a half inches in length from the stomach of an insane woman about three months after it had been swallowed. The prongs of the fork had penetrated through the stomach wall into the wall of the abdomen. Dr Radestock operated on a prisoner who had attempted suicide. Twenty three days afterwards the latter had swallowed a rubber cuff, five pieces of glass (each as broad as the finger) and ten pieces of wood (each as long as the finger and as thick as the thumb). It was necessary to open the intestine to remove some of these. After recovery from the first operation he again swallowed similar pieces of wood, which had to be removed from the intestine. Dr M. H. Richardson operated on a lady who had swallowed on three consecutive days a gold pencil-case, a large open safety pin, a steel crochet needle five inches in length and several common pins. The safety pin was the only foreign body found in the stomach and had perforated its coats. One pin and the pencil case were subsequently passed per anum, the other things were not again seen. Perier recorded the case of a man who had swallowed a teaspoon, he proved its presence in the stomach by means of an electric exploring instrument and afterwards removed it by operation. Mr D. Lowson removed a skewer seven inches and a half in length which had penetrated through the prietres, but could not be removed without operation on account of a piece of clay pipe which was attached to it in a transverse direction. We must not omit reference to the performance of this operation for

the removal of masses of hair forming tumours occupying the interior of the stomach, they hardly come under the same category as the cases above enumerated, the formation of the masses being slow and their diagnosis difficult, the results obtained by Knowsley Thornton, Schönborn and John Berg in the three recorded cases were brilliant. In a recent number of THE LANCET we referred to some instances in which gastrotomy was performed to enable foreign bodies impacted in the lower part of the oesophagus to be removed.

Mrs S—, aged sixty eight, was admitted into the Lincoln County Hospital on Tuesday, Dec. 13th, 1892, as she said she had "swallowed a razor" for the purpose of destroying her life. She was in a very depressed state of mind, frequently saying she was "lost" and that "there was no hope for her." She told her tale clearly and Mr Cant felt convinced she had done as she said. The friends, however, were doubtful, they thought she must be under some delusion, especially as they had, so far as they knew, removed everything with which she could destroy herself. The razor case had, however, been found empty. Thirty years ago she had attempted suicide and had been detained for some time in an asylum. It was elicited from her friends that she was a "bleeder." She had been bleeding from the gums and mouth for five or six weeks before her admission into the hospital. On examining the pharynx a slight abrasion was found and from this blood frequently came. The tongue was cracked and sore. This continued so throughout. No symptoms or signs of the razor could at first be detected, so it was decided to watch the case, also to endeavour to determine experimentally the presence of the razor. Dr Belcher, science master to the Science and Art Schools, Lincoln, attempted to do this by means of the compass needle, having first magnetised the razor, this gave no satisfactory result. Mr Cant then ordered her twenty drops of dilute hydrochloric acid. After an hour the stomach was washed out, the washings collected, filtered, evaporated down and redissolved. The presence of iron in a large quantity was shown by the Prussian blue test. At a consultation held on Saturday, Dec. 17th, it was decided to wait for further proof. On Sunday morning (the 18th) the end of the razor could be clearly felt, fixed at the pyloric end of the stomach. On Sunday night she had vomiting and slight pain. It was decided to operate on Monday, the 19th, at 12.30 p.m.

Operation.—No food was given by the mouth for eighteen hours before the operation, the patient being fed on nutrient enemata. Fifteen minutes before the operation one sixth of a grain of morphia was administered subcutaneously and A.C.E. mixture was given by Mr Watkins, the house surgeon, whose unremitting care together with that of the nurses deserve the highest praise. The skin of the abdomen, as also everything that would be likely to come in contact with the wound, was made aseptic. An incision four inches long was made in the middle line above the umbilicus directly down to the peritoneum. This after complete cessation of the bleeding, was opened on a director. The left lobe of the liver came into view and on passing the finger down to the stomach Mr Cant felt the razor lying lengthwise therein, the narrow end in the cardiac region. The finger was passed behind the stomach, which was with some difficulty brought forward into the wound, with the narrow end of the razor projecting in it. A small opening was made into the stomach so that the small end of the razor projected through it. A little of the gastric juice escaped, but none was allowed to get into the abdominal cavity. There was some bleeding from the stomach wound and it was necessary to tie a small artery. The razor, six inches and a half long, was then drawn through the wound. Hot pads of sal alembroth wool were constantly applied to prevent any chilling of the abdominal contents. The stomach wound was then stitched up with a double row of eight fine silk sutures (an ordinary sewing needle being used). This was done by Czerny's method. The stomach was then returned. The abdominal incision was sutured with silk and dressed antiseptically. The patient was then removed to a warm bed and fed with prurient milk enemata every four hours (an egg was added on Dec. 21st to every half pint of milk). These she retained throughout. Nothing whatever was given by the mouth, but it was occasionally sponged out with cold water till 9.30 p.m., when she had a teaspoonful of toast-water. This was repeated occasionally as she had great craving for drink. She remained comfortable and slept at intervals, she was pleased when she heard the razor had been removed and her mental condition improved from that time. She voided urine naturally and thirteen hours

after the operation passed flatus. The bowels were moved naturally the day after the operation. Thirty hours after the operation she vomited one ounce of dark blood, for which four grains of acetate of lead were given in water. One sixth of a grain of morphia was given hypodermically, occasionally, when the patient was restless and for the hæmorrhage. Midday on Dec. 21st the bowels were freely moved and again on Dec. 22nd. Small quantities of blood were vomited at intervals during the day of the 22nd, for which acetate of lead was again administered. Next day (the 23rd) ten grains of gallic acid were ordered for the hæmorrhage and this was repeated three times at intervals. At 8.30 A.M. on Dec. 23rd the bowels were again moved. At 9.30 A.M. the wound was dressed and found to be nearly healed. The bowels became rather relaxed and opium was given at intervals. A teaspoonful of Brand's essence of beef was given every hour by the mouth. There was no further vomiting and at 6 P.M. her condition seemed in every way favourable. She complained of slight pain early in the morning of Dec. 24th and was very weak and faint. She became much worse at 4 A.M., her strength failing. She gradually sank till she died at 8.45 A.M. Her temperature never rose above 99° and the pulse remained at about 92, till near the end.

Necropsy.—On examination an abscess was found in the abdominal wall from which a small amount of pus escaped externally, but there was no connexion with the abdominal cavity. On opening the abdomen the intestines and peritoneum were glistening and normal. A small amount of lymph was thrown out round the wound of the stomach. This caused slight adhesion to the under surface of the liver and the abdominal wall. There was no escape of the stomach contents. The stomach was found empty and natural and the wound closed and healing. All the other organs of the chest and abdomen were healthy except the heart, which showed extensive mitral disease. The cause of death seemed to be exhaustion due to the hæmorrhage she was suffering from previously to swallowing the razor and to the slight hæmorrhage before and after the operation, to the necessary restraint from food to a person of her advanced age, and to the heart complication.

Medical Societies.

EPIDEMIOLOGICAL SOCIETY

A MEETING of this Society was held on Dec. 21st, Dr F J Payne, President, in the chair.

Dr WHITELEGGE read a paper, illustrated by numerous lantern exhibitions of statistical tables, on Epidemics of Measles, Major and Minor. Measles was, he said, a disease of the bacteriology of which we knew nothing and which seemed wholly uninfected by the progress of sanitation. There were everywhere a summer and winter wave the former being the higher, except in London and a few other towns. In London the maxima occurred in June and December, in New York they were later—viz., July and February. Dr Spottiswoode Cameron had observed a high barometer, scanty rainfall and low humidity to accompany a high mortality. The minor epidemics recurred as a rule about every two years in Europe. The intervals in London, Liverpool, Manchester, Nottingham, Bolton &c. had gradually fallen from three to one and a half years. In isolated communities in which the disease died out altogether after an epidemic, there was no trace of periodicity. In the few towns in which notification had been adopted it was seen that contrary to the inference suggested by returns of deaths alone the disease was never entirely absent, and an analysis of the cases in the several districts or wards showed that the progress of an epidemic was rather a smouldering than an explosion. The type of the disease rarely changed during an epidemic and higher mortalities were mostly due to the state of the weather, the supervention of pneumonia or the co-existence of other specifics. The death rate or case mortality, however varied in different places and years from 0 to 10, 20 or even 30 per cent, though these higher mortalities were seldom if ever met with in these countries. They had been observed only under very unfavourable conditions. In all such epidemics the deaths were mainly due not to the disease itself, but to the surroundings, hardships or improper treatment, or to excessive suscep-

tibility of population. We never, however, observed a change of type in the course of an epidemic, whether of intensification (as Dr Thorne Thorne has shown in the case of diphtheria) or of lessening severity, as was familiar in those of scarlet fever and cholera, and as a rule the intensity of measles was inversely as the extent of the epidemic. In London the ratio of the deaths from measles to those from all causes showed the recurrence of biennial epidemics, with alternate longer series of higher and lower mortalities. The Sunderland tables were the most complete and instructive, they showed a biennial recurrence since 1876, with a remarkable rise from the winter of 1884-5, when the maximum case mortality of 29 per cent was reached. In conclusion, Dr Whitelegge said that the difference between major and minor epidemics consisted in the fact that the latter, whether large or small, and over wide or narrow areas, occurred every two or three years, as it were mechanically, while occasionally over wide or narrow areas successive minor epidemics, owing to a progressive intensification of the virus, became more and more virulent, till they constituted what he had called major epidemics. But the keynote of the epidemiology of measles was its stability of type, as instability was characteristic of diphtheria, and this might serve to explain the little variation in its clinical characters, its little tendency to live out of the body or in artificial culture fluids, in water, milk &c., and the want of success attending all attempts to communicate the disease to the lower animals.

The President, Mr Murphy, Dr S Coupland and Dr Willoughby took part in the discussion.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

THIS Society met on Dec. 19th, 1892, Mr Shurley Murphy, President, in the chair.

Dr THURSFIELD read a paper on Deaths of Mothers in Childbed considered as Preventable Mortality. These deaths included two distinct classes (1) Those from "puerperal fever" and (2) those due to accidents of childbirth, some of which were perhaps inevitable, but the greater number were owing to the want of proper obstetric attention and skill. The death rates per 10,000 births in England and Wales for each quinquennium from 1851 to 1890 were. Total deaths, 49, 48, 46, 54, 39, 49, 45, puerperal fever, 15, 15, 16, 15, 24, 17, 28, 24, accidents of childbed, 34, 30, 32, 31, 20, 22, 21, 21. For the year 1890 they were respectively 48, 6, 22, 3 and 26, 4. The apparent increase in those from puerperal fever since 1881 was possibly due to the inquiries instituted into suspicious returns of peritonitis and pyæmia, but the fact remained that 50 per cent of the deaths in childbed were from this cause and therefore preventable. There was, however, in different districts a remarkable difference, not only in the total mortality, but in the relative proportion of those from the two causes—lowest in London and the home counties and highest in the thirty peopled agricultural and mining districts, with a preponderance of puerperal fever in the urban and of accidents in the rural populations, notwithstanding the prevalence in towns of rickets—a frequent cause of difficult parturition. As typical populations he took London, Manchester, the North Wales and the south western registration districts, in which the mean death rates per 10,000 births for the years 1881-90 were—

England and Wales	47.3	25.9	--	21.3
London	29.1	14.4	--	15.3
Manchester	52.0	31.3	--	20.0
N. Wales Counties	67.3	32.6	--	24.7
S.W. Group of Counties	43.6	20.5	--	22.2

The excessive mortality from accidents in the rural districts, where the total deaths are below the average, was noteworthy and explicable only by the want of skilled attendance. "Puerperal fever" was not a specific disease *in generis*, but a collective designation of septicæmia, pyæmia, erysipelas &c., occurring during the puerperal process, the septic material being derived from external sources, from other cases or from auto-infection. It was virulent and persistent in the extreme, but the analogy of surgical septicæmia justified us in believing it to be wholly preventable, or nearly so. What he wished to emphasize was the necessity for the instruction of nurses and midwives in the antiseptic treatment of all cases and in the recognition of those which called for skilled medical assistance.

Dr WIGHTWICK maintained that all post mortem examinations should be made by special pathologists

Dr SYKES was inclined to attribute most cases occurring among the poor to the neglect of disinfection of bedding after infectious diseases, especially typhoid fever

Dr WILLOUGHBY, while strongly insisting on the septic origin of all puerperal fever, which he would have called by its proper name of puerperal septicæmia, agreed with Dr Sykes as to the necessity for disinfection

On the motion of Dr GIBSON, seconded by Dr WOODFORD, it was resolved that the Society should confer with the Obstetrical Society on the extension of instruction in midwifery

Dr GARRETT then read a paper on the "Spontaneous Pollution of Water originally Pure in Storage Reservoirs." The water supply of Cheltenham was, he said, drawn from two sources the river Chelt, and from openings in the oolite of the Cotswold hills. The latter was moderately hard (12°—16°), but of extraordinary purity, yielding only 0.04 per million of albuminoid ammonia and absorbing no more oxygen than ordinary distilled water. One of the reservoirs was covered, the other two were open. Complaints having been made that the town water had a "fishy taste" suspicion fell on the Chelt as the less pure, but it was soon ascertained that the fault lay with the open reservoirs on Hewlett's Hill and that the cause was the growth of Chara, which was not found in the covered reservoir, since like all plants forming chlorophyll it needed light. Dr Garrett exhibited specimens of the Chara. It grew luxuriantly in the early summer but in autumn broke up to a great extent, rendering the water turbid with its disintegrated and decomposing tissues which swarmed with organisms of every kind and emitted odours, faecal and other. Dr FURROW of Harward had referred these odours to *Lyngbya Beggiatonia* and *Nostoc* respectively, and Dr ADAMS of Bolton ascribed the stale fish smell to *Converva Bombycina*, but this last was not found at Cheltenham, where the *Lyngbya* abounded. The Chara softened the water remarkably. Peaty waters containing vegetable matter were acid, but this was slightly alkaline. Attempts to exterminate the plant were unsuccessful, and Dr Garrett had advised the use of the covered reservoir only, and that when it was necessary to have recourse to the others, that the water should not be allowed to remain in them any length of time.—Drs BOSTOCK, HILL, THRESH, WILLOUGHBY and others took part in the discussion.

PROVINCIAL MEDICAL SOCIETIES

BRADFORD MEDICO CHIRURGICAL SOCIETY.—A clinical meeting was held on Dec 20th 1892, Dr Bell, President, in the chair. Dr S. LODGE showed a young woman aged twenty-four suffering from Chronic Oesophagitis. For four years she had suffered pain on swallowing solids. The tenderest part appeared to be on a level with the lower third of the sternum. There was an excessive appetite and pyrosis, but no other evidence of disease. She was relieved by restriction to liquids and the exhibition occasionally of a little bismuth. Dr Lodge also brought forward a case in which a mastoid operation was performed. There had been epistaxis with signs of meningitis, including fever, slow pulse and double optic neuritis. The mastoid cells being opened the patient steadily improved and the neuritis and other signs disappeared. In another case shown with Facial Palsy Dr Lodge had opened the mastoid, scraped out some dead bone and the paralysis disappeared.—Dr MAJOR showed a patient probably affected by lead. The lower branches of the facial nerve were paralysed, whilst the upper were free. The paralysed palate responded readily to direct stimulation. Dr Major also showed two patients, both suffering from early General Paralysis. There was no syphilitic history obtainable and neither had grandiose delusions. He strongly advocated surgical treatment of all cases with much headache, as improvement was to be expected.—Dr BELL showed a case of Primary Shrinking of the Conjunctival Sac until the eye was closed in and the eyeball immovably fixed between the closed and adherent lids, he had shown a similar case to the Society sixteen years ago. A few others had been reported since especially in connexion with pemphigus, but in neither of his cases had there been this association. A case of Primary Calcareous Degeneration of the Cornea was also shown by Dr Bell, a few such had lately been reported. It began on the upper part of the cornea, just under

the surface, which was smooth and covered by a layer of epithelium, there was neither pain nor ulceration. The area of the pupil was nearly covered. This case was unique in that absorption of the calcareous matter was progressing in the parts covered by the lids.—Dr APPELBYARD showed Seven Elbows in which he had practised excision with varying results. In one case "relax" paralysis had ensued with loss of the use of the deltoid and muscles passing over the elbow, except those attached to the inner condyle. There was no loss of sensation. Other cases of interest were also shown at this meeting.

MANCHESTER CLINICAL SOCIETY.—At a meeting held on Dec 20th, 1892, Dr T. C. RAILTON M.D., M.R.C.P., occupied the chair.—Dr MILLIGAN showed several patients suffering from the presence of Naso-pharyngeal Adenoids. A short historical sketch of the disease was given. The histological characters of adenoid tissue were discussed and microscopic specimens shown. It was pointed out that the disease should be considered as the local manifestation of a dyscrasia closely akin to scrofula and that it was responsible for at least 50 per cent of the nasal catarrhs of childhood. The symptomatology of the affection was briefly touched upon, special mention being made of secondary affections of the ear. Great stress was laid upon the importance of early and radical surgical interference, especially in those children who at the same time suffered from recurrent attacks of deafness and earache. It was pointed out that even although the growths did show a marked tendency to atrophy during adolescence the surgeon was not justified in waiting for this atrophic change to take place, seeing that during the period of retrogression serious and irreparable changes might happen to the organ of hearing. The various methods of removing the growths were then discussed and the requisite instruments shown.—Dr STELL related two cases of Aortic Incompetence illustrative of the prognosis of the disease. The first case was that of a man aged thirty-two who was free from syphilis or gout and had not suffered from rheumatism or chorea, but had been exposed to making great physical efforts. The patient suffered during the last few months of his life from angina pectoris and dyspnoea, but had not developed dropsy or engorged liver. He was able to continue his occupation till the day of his death which resulted from subacute heart failure. At the necropsy the aortic valves were found thickened and shrunken and the aorta sound except in the immediate neighbourhood of the valves. The orifices of the coronary arteries were implicated and much contracted. The second case was that of a large, powerfully built young man who had had rheumatic fever when a lad. Physical examination revealed a great amount of aortic incompetence. The patient was for years under observation, suffering occasionally from the symptoms of dyspnoea, dropsy and engorged liver, but of no great severity. These symptoms were always readily removed by treatment and he resumed his work. During the last few years of his life his health had improved and he remained free from dropsy and was able to do his work without interruption. Unfortunately he contracted enteric fever, of which he died. At the post-mortem examination the great reactive capacity of his heart in the presence of a grave lesion was explained by the coronary arteries not being involved in disease and by one of them being of unusually large size. A third case was mentioned. It was that of a woman who died of angina pectoris. The aorta was dilated, the valves incompetent and the orifices of the coronary arteries much contracted. Specimens from the three cases were shown.—Dr ERNEST S. REYNOLDS showed a case of Chronic Hysteria in a female aged twenty-nine years. The attack had come on suddenly when she was fourteen years old, and she had practically remained in the same condition ever since. She showed very marked hysterical mutism and spasm of the right half of the tongue and of the left arm and leg. He also related a case of Landry's Paralysis, the patient having recently died. She was admitted to the hospital suffering from bronchitis and in a few days she lost the power of standing. The legs then became completely paralysed and also the large muscles of the arms. The toes and fingers could be moved almost to the last. On the eleventh day the respiratory muscles were attacked and she died on the twelfth day of the disease.

NOTTINGHAM MEDICO CHIRURGICAL SOCIETY.—On Dec 21st, 1893, Mr R. C. CHICKEN, F.R.C.S., presided at a meeting of this Society. Mr GRAY, F.R.C.S., showed a woman aged sixty-three with an enormous Cystic Enlargement of the Left Breast, probably sarcomatous.—Dr HEELIS

To illustrate Sir Andrew Clark's Lecture on "Cases of Fibroid Phthisis, and
Remarks on Them"

Dr WIGHTWICK maintained that all post mortem examinations should be made by special pathologists

Dr SYKES was inclined to attribute most cases occurring among the poor to the neglect of disinfection of bedding after infectious diseases, especially typhoid fever

Dr WILLOUGHBY, while strongly insisting on the septic origin of all puerperal fever, which he would have called by its proper name of puerperal septicæmia, agreed with Dr Sykes as to the necessity for disinfection

Dr WILLOUGHBY, while strongly insisting on the septic origin of all puerperal fever, which he would have called by its proper name of puerperal septicæmia, agreed with Dr Sykes as to the necessity for disinfection

On the motion of Dr GIBBON, seconded by Dr WOODFORD, it was resolved that the Society should confer with the Obstetrical Society on the extension of instruction in midwifery

Dr GABRETT then read a paper on the "Spontaneous Pollution of Water originally Pure in Storage Reservoirs" The water supply of Cheltenham was, he said, drawn from two sources—the river Chelt, and from openings in the oolite of the Cotteswold hills The latter was moderately hard (12° – 16°), but of extraordinary purity, yielding only 0.04 per million of albuminoid ammonia and absorbing no more oxygen than ordinary distilled water One of the reservoirs was covered, the other two were open. Complaints having been made that the town water had a "fishy taste" suspicion fell on the Chelt as the less pure, but it was soon ascertained that the fault lay with the open reservoirs on Hewlett's Hill and that the cause was the growth of Chara, which was not found in the covered reservoir, since like all plants forming chlorophyll it needed light. Dr Garrett exhibited specimens of the Chara It grew luxuriantly in the early summer, but in autumn broke up to a great extent, rendering the water turbid with its disintegrated and decomposing tissues, which swarmed with organisms of every kind and emitted odours, fecal and other Dr Farrow of Harvard had referred these odours to Lyngbya Beggonia and Nostoe respectively, and Dr Adams of Bolton ascribed the stale fish smell to Conerva Bombycina, but this last was not found at Cheltenham, where the Lyngbya abounded The Chara softened the water remarkably Peaty waters containing vegetable matter were acid, but this was slightly alkaline Attempts to exterminate the plant were unsuccessful, and Dr Garrett had advised the use of the covered reservoir only, and that when it was necessary to have recourse to the others, that the water should not be allowed to remain in them any length of time—Drs Bostock Hill, Thresh, Willoughby and others took part in the discussion.

PROVINCIAL MEDICAL SOCIETIES

BRADFORD MEDICO CHIRURGICAL SOCIETY—A clinical meeting was held on Dec. 20th 1892, Dr Bell, President, in the chair Dr S LODGE showed a young woman aged twenty four suffering from Chronic Oesophagitis. For four years she had suffered pain on swallowing solids The tenderest part appeared to be on a level with the lower third of the sternum. There was an excessive appetite and pyrosis but no other evidence of disease She was relieved by restriction to liquids and the exhibition occasionally of a little bismuth. Dr Lodge also brought forward a case in which a mastoid operation was performed. There had been epistaxis with signs of meningitis including fever slow pulse and double optic neuritis The mastoid cells being opened the patient steadily improved and the neuritis and other signs disappeared. In another case shown with Facial Palsy Dr Lodge had opened the mastoid, scraped out some dead bone and the paralysis disappeared—Dr MAJOR showed a patient probably affected by lead. The lower branches of the facial nerve were paralysed, whilst the upper were free The paralysed palate responded readily to direct stimulation Dr Major also showed two patients both suffering from early General Paralysis There was no syphilitic history obtainable and neither had grandiose delusions He strongly advocated surgical treatment of all cases with much headache, as improvement was to be expected—Dr BELL showed a case of Primary Shrinking of the Conjunctival Sac until the eye was closed in and the eyeball immovably fixed between the closed and adherent lids, he had shown a similar case to the Society sixteen years ago A few others had been reported since, especially in connexion with pemphigus, but in neither of his cases had there been this association. A case of Primary Calcareous Degeneration of the Cornea was also shown by Dr Bell, a few such had lately been reported It began on the upper part of the cornea, just under

the surface, which was smooth and covered by a layer of epithelium, there was neither pain nor ulceration The area of the pupil was nearly covered This case was unique in that absorption of the calcareous matter was progressing in the parts covered by the lids—Dr APPLEBY showed Seven Elbows in which he had practised excision with varying results In one case "reflex" paralysis had ensued with loss of the use of the deltoid and muscles passing over the elbow except those attached to the inner condyle There was no loss of sensation Other cases of interest were also shown at this meeting

MANCHESTER CLINICAL SOCIETY—At a meeting held on Dec 20th, 1892, Dr T C RAILTON, M.D., M.R.C.P., occupied the chair—Dr MILLIGAN showed several patients suffering from the presence of Naso-pharyngeal Adenoids A short historical sketch of the disease was given The histological characters of adenoid tissue were discussed and microscopic specimens shown It was pointed out that the disease should be considered as the local manifestation of a dyscrasia closely akin to scrofula and that it was responsible for at least 50 per cent. of the nasal catarrhs of childhood The symptomatology of the affection was briefly touched upon, special mention being made of secondary affections of the ear Great stress was laid upon the importance of early and radical surgical interference, especially in those children who at the same time suffered from recurrent attacks of deafness and emaciation It was pointed out that even although the growths did show a marked tendency to atrophy during adolescence the surgeon was not justified in waiting for this atrophic change to take place, seeing that during the period of retrogression serious and irreparable changes might happen to the organ of hearing The various methods of removing the growths were then discussed and the requisite instruments shown—Dr STEELL related two cases of Aortic Incompetence illustrative of the prognosis of the disease. The first case was that of a man aged thirty two who was free from syphilis or gout and had not suffered from rheumatism or chorea, but had been exposed to making great physical efforts The patient suffered during the last few months of his life from angina pectoris and dyspnoea, but had not developed dropsy or engorged liver He was able to continue his occupation till the day of his death, which resulted from subacute heart failure At the necropsy the aortic valves were found thickened and shrunken and the aortic sound except in the immediate neighbourhood of the valves The orifices of the coronary arteries were implicated and much contracted The second case was that of a large, powerfully built young man who had had rheumatic fever when a lad Physical examination revealed a great amount of aortic incompetence The patient was for years under observation, suffering occasionally from the symptoms of dyspnoea, dropsy and engorged liver but of no great severity These symptoms were always readily removed by treatment and he resumed his work During the last few years of life his health had improved and he remained free from dropsy and was able to do his work without interruption. Unfortunately he contracted enteric fever, of which he died. At the post-mortem examination the great reactive capacity of his heart in the presence of a grave lesion was explained by the coronary arteries not being involved in disease and by one of them being of unusually large size. A third case was mentioned. It was that of a woman who died of angina pectoris The aorta was dilated, the valves incompetent and the orifices of the coronary arteries much contracted. Specimens from the three cases were shown—Dr ERNEST S REYNOLDS showed a case of Chronic Hysteria in a female aged twenty nine years The attack had come on suddenly when she was fourteen years old, and she had practically remained in the same condition ever since She showed very marked hysterical mutism and spasm of the right half of the tongue and of the left arm and leg He also related a case of Landry's Paralysis the patient having recently died She was admitted to the hospital suffering from bronchitis and in a few days she lost the power of standing The legs then became completely paralysed and also the large muscles of the arms The toes and fingers could be moved almost to the last On the eleventh day the respiratory muscles were attacked and she died on the twelfth day of the disease.

NOTTINGHAM MEDICO CHIRURGICAL SOCIETY—On Dec 21st, 1893, Mr R C CHICKEN, F.R.C.S., presided at a meeting of this Society Mr GRAY, F.R.C.S. showed a woman aged sixty three with an enormous Cystic Enlargement of the Left Breast, probably sarcomatous—Dr HEELIS

read a paper on Puerperal Fever. He said the theory that puerperal fever is always caused by direct infection by attendants and is always preventable by antiseptic precautions was not adequate to explain all cases. The genital tract cannot be kept aseptic with the same certainty as a surgical wound. Preventive treatment consisted in the strict observance of antiseptic rules, details of which were given. In addition to suitable diet and medication the following local treatment was adapted to the developed disease: (1) Syringing, (2) swabbing out the uterus with carbolic acid, (3) combined curetting and swabbing. Where the tubes or ovaries were the seat of suppuration they should be removed by operation.—Dr FFXENELL read notes of a case where the patient was exposed during the puerperal period to infection by scarlet fever in concentrated form and recovered without any febrile symptoms.—Dr ELDER said puerperal fever had been known to be carried by attendants and nurses for the last hundred years and modern science and practice quite bore out this view. He deprecated the common practice of making the obstetric bag the receptacle for catheters and other instruments of doubtful purity. He pointed out the diminished mortality in lying in hospitals following on careful attention to hygienic rules and the use of antiseptics.—Dr MICHIE thought puerperal fever was often due to local inflammatory conditions, such as metritis and salpingitis, which in some cases existed before labour. In such cases laparotomy was the remedy.—Dr HANDFORD thought autogenetic cases were due to the action of germs, the source sometimes being undiscoverable. Laparotomy might sometimes be required, but he thought a great many cases recovered in the long run when left alone.—Mr NESBITT remarked that in his district puerperal fever was a notifiable disease.—Specimens Dr MICHIE showed the following removed by operation with successful results: Two Ovarian Tumours with twisted Pedicles, a Ruptured Ovarian Cyst, Commencing Cystic Disease of Ovary, a small Paroöphoric Cyst, a small Parovarian Cyst.

PLYMOUTH MEDICAL SOCIETY.—Mr GEORGE JACKSON read a paper before this Society on Dec 21st, 1892, on the Medical Defence Societies. After pointing out the dangers to which medical men were exposed by false accusations, blackmailing &c. he showed the necessity of everyone in active practice joining such a society, which would protect him and if necessary defend him in the law courts from such accusations. The following resolutions were carried—viz, (1) that in the opinion of this meeting it is very desirable that a branch of a medical defence society be formed, and (2) that a branch of the London and Counties Medical Protection Society, Limited, be formed for this district. A small committee was appointed to carry out the details and to call shortly a general meeting of the practitioners of the neighbourhood to inaugurate a branch of the London and Counties Medical Protection Society.

ROYAL ACADEMY OF MEDICINE IN IRELAND

PATHOLOGICAL SECTION

A MEETING of the Section of Pathology was held on Dec 2nd, Dr Frazer in the chair.

Diffuse Cerebro-spinal Sclerosis.—The PRESIDENT read a paper on a case of this affection that had occurred under his care at the Mater Misericordiae Hospital. Most extensive lesions were found post mortem by Dr M Weeney, partaking of the character of disseminated sclerosis and of chronic myelitis. Dr M Weeney then described at length the lesions found in the part of the central nervous system that had been examined—viz. from the lower end of the cord to the upper part of the medulla, and demonstrated a large series of sections prepared mostly by Weigert's hematoxylin method.—Dr FRAZER said that Dr M Weeney's paper was to be considered as a report of half the case only and that the account of the remainder was to be expected at a future meeting.

Adenoma of the Kidney.—Mr CONOLLY NORMAN read a paper on adenoma of the kidney and exhibited a specimen of that affection. Both the kidneys were curiatic the left extremely so. Mr Norman believed that the most satisfactory explanation was that of Sabourin, who held that curiatic material in the proliferated epithelium of the convoluted tubule.—The PRESIDENT asked Mr Norman if the tumour

might not arise from some of those cystic foci which are so commonly met with in cases of contracted kidney, and also what was the condition of the heart, and of the left ventricle in particular.—Mr NORMAN, in reply, said that in one of the "granulations" of Bright he found a number of dilated tubes the epithelium of which appeared to be proliferating. The patient's heart was hypertrophied as a whole and the left ventricle in particular.

SURGICAL SECTION

A meeting of the Surgical Section was held on Dec. 9th, Dr E Hamilton, President, in the chair.

Two Cases of Disease of Mastoid and Petrous Portions of Temporal Bone in connexion with Disease of the Ear.—Mr DOYLE brought forward these two cases. In the first case chronic suppurative disease of the middle ear and the mastoid cells had eaten a circular opening through the right temporal bone, it communicated with the middle fossa of the cranium, producing softening and abrasion of the under surface of the temporo-sphenoidal lobe of the brain. The second case was operated on for caries and mastoid periostitis in September last, and is still under treatment and progressing favourably.

Cancer of the Rectum.—Dr BALL read in abstract a communication on cancer of the rectum. Dealing with the pathology of the subject, Professor SCOTT gave a lantern display of micro photographs, chiefly from Dr Ball's cases, illustrating the disease. Dealing with the diagnosis Dr BALL laid great stress on the importance of early recognition and on the fact that many cases were treated as chronic dysentery where a digital examination would have shown that cancer existed. Having discussed the limits of an excision of the disease he presented a table showing the results of excision in nine cases in his practice. Regarding colotomy the opinion was expressed that in a large proportion of cases of cancer unsuitable for excision obstruction never became a prominent symptom, and that these cases were much better left without operation. Colotomy was, however clearly indicated where obstruction was commencing, colotomy should be had recourse to early, before any of the secondary changes due to obstruction were marked.—The PRESIDENT endorsed the statement of Dr Ball that in many cases diseases of the rectum are allowed to go on for a very long time without being satisfactorily diagnosed.

Dr Thomson, Dr Franks, Dr Thornley Stoker, Mr Myles Mr Tobin, Dr Bennett and Dr Brooks took part in the very interesting discussion which followed.

OBSTETRICAL SECTION

A meeting of the Obstetrical Section was held on Nov 25th, Dr Horne, President, in the chair.—Mr JOHN McCULLAGH and Mr MCARDLE exhibited cases of Spina Bifida, one treated by iodo-glycerine, the other cured spontaneously.—Dr SMITH showed a specimen of Hydrops Follicularum, a large Dermoid Cyst, a Multilocular Ovarian Tumour, a Sloughing Fibromatous Polypus and a Parovarian Cyst, all removed by operation and all the patients recovered.—The PRESIDENT exhibited an Ovarian Tumour, removed on account of axial rotation, with peritonitic symptoms. The patient recovered. Mr McArdle and Dr Smyly took part in the discussion.—Dr FLINN exhibited a Parovarian Cyst removed by operation, the patient recovered.—Dr E HASTINGS TWEEDY showed a Blighted Ovary, which escaped six hours after delivery at term.—Dr KIDD inquired whether the foetal placenta was connected with the placenta proper.—Dr TWEEDY replied that he had not found any connexion.—Mr McArdle exhibited a specimen of the Labia Majora removed for perforating ulcer. There was glandular infection, and the President, Mr Smith, Mr Tobin, Dr Smyly and Dr Parsons joined in the discussion.—Mr MCARDLE next exhibited a Renal Cyst which simulated ovarian tumour. The patient did well.—Mr TOBIN bore witness to the great size of the tumour.—Mr MCARDLE then gave details of a case in which Intruterine Arrest of Development had taken place he contended, as a result of injury to the mother by railway accident.—Dr McCullagh, Dr Smith, Dr Smyly, and Mr Broomfield joined in the discussion. The opinion of the meeting as to the etiology of the case was divided.—Mr MCARDLE gave details of a case in which Intruterine Arrest of Development occurred as a result of injuries sustained by the mother in a railway disaster. At birth it was found that the spinal canal was incomplete, except at the middle dorsal region. The head also showed an arrest of development. The right hip-joint was also undeveloped. It seemed as if the injury to the mother had checked growth,

leaving the parts described in the condition of development arrived at before the injury—Mr McCULLAGH said the case of spina bifida he had shown that evening was ascribed by the mother to a blow on the back between the third and fourth months of pregnancy—Dr SMITH said he believed that nervous impressions sometimes produced these strange deformities—Dr SMYLY did not believe in it at all, the case was probably a remarkable coincidence and nothing more—Mr BROOMFIELD said there were other organs that were equally tender in this stage of fetal life and he failed to see why disease should concentrate itself altogether on the laminae of the vertebrae—Mr MCARDLE said the object he had in bringing the case forward was to elicit the opinions of his *confères* on the subject

Reviews and Notices of Books.

The Life and Works of John Arbuthnot, M.D., Fellow of the Royal College of Physicians. By GEORGE A. AITKEN. Oxford: The Clarendon Press, 1892.

ENGLISH literature is not without its "opprobria," amongst the most flagrant of which is the want of any adequate biography of Arthur Jonston, M.D., physician to King Charles I and the worthy rival as a Latin poet of George Buchanan, whose far famed version of the *Psalms* he is believed by many scholars to have equalled, if not surpassed. Another of "medicine's forgotten worthies" was Dr John Arbuthnot, in Samuel Johnson's opinion "the first man" among the wits of Queen Anne's reign, "an excellent physician" of "deep learning" and of "much humour." The "opprobrium" in Arbuthnot's case has now we are glad to say, been for ever wiped out by a compatriot, on whose narrative of his life and edition of his works we shall have something to say presently, but in Arthur Jonston's case the "opprobrium" still stands, although, if report speaks truly, it will not long be a blemish on our literary escutcheon, a monograph on that able consultant and exquisite Latinist and poet having been promised, also by a compatriot eminently qualified for the task—Sir William Duguid Geddes, Principal of the University of Aberdeen.

Arbuthnot was a typical specimen of the young Scottish cadet—"the penniless lad with a long pedigree"—of whom Thackeray speaks admiringly in his sketch of Smollett—who came up to the great world, like Dugald Dalgetty with the "learning acquired at the Manschal College of Aberdeen," with his "gentle blood and designation together with a pair of stalwarth arms and legs conform," to push his way as "a cavalier of fortune." Whether, indeed, Aberdeen can claim Arbuthnot as an alumnus does not amount to more than a "moral certainty," but we know that he had acquired mathematics enough to begin life as a teacher of the same in London and to write a book, "Of the Laws of Chance" in which his proficiency in the science and his general high culture are manifest. After this we find him, on Oct. 6th, 1694, two years subsequently to the publication of that book, entering University College, Oxford, as Socio Commensalis or Fellow Commoner—a fact unearthed for the first time by his biographer—and acting there as companion and private tutor to a young gentleman of fortune. The next glimpse we catch of him—for glimpses are nearly all that his most patient and circumspect biographer can give us of his early years—is at St. Andrews, where he was admitted to an *ad eundem* degree in medicine in September, 1696 at the age of twenty-nine, his "thesis medica" being "De Secretione Animi." Where he received the professional education and the degree that qualified him for the St. Andrews' diploma his biographer fails to tell us, but that his medical knowledge was sound and his classical learning considerable we may infer from what George Hamilton Principal of St. Andrews, wrote three days after his graduation, to Dr Charlett. The bearer, Dr Arbuthnot, is a gentleman of

great merit, that has acquit himself extraordinarily well both in his private and public tryalls in solemn meetings of several Professors and Doctors of Medicine towards his promotion." His headquarters were now in London, where we find him engaged in scientific and classical authorship as a foil to the professional practice in which he had come to the front. Elected a Fellow of the Royal Society on St. Andrew's Day, 1704, he was next year, on Oct. 30th, appointed Physician Extraordinary to Queen Anne by Her Majesty's special command "in consideration of his good and successful services perform'd as Physician to His Royal Highnesse," Prince George of Denmark, who, it appears, "taken suddenly at Epsom, had been successfully treated by Arbuthnot, who happened to be on the spot and who was always afterwards employed by the Prince as his physician." His biographer might have added that the old manor house at Easthill, Windsor, built by Prince George for the Queen, was often visited by Dr Arbuthnot, who attended Her Majesty's children there and caused (so says local tradition) the well known iron stanchions to be placed on the nursery windows as a safeguard against their falling out on to the lawn below. This picturesque house, it seems, is already doomed to disappear before the extension of London. But to return. Arbuthnot was now one of the most considerable men in town, a scholar of scholars, a physician of physicians, the wittiest of the witty and a prime mover of Jacobite policy in the camrilla of which Bolingbroke and Atterbury were ruling spirits. All this part of his career is admirably set forth by his biographer, whose profound knowledge of the literature and life of Queen Anne's reign serves him in enviable stead. The doctor's familiarity with Pope, Swift and Gay is illustrated by skilful selections from the correspondence of these with other contemporary wits and public men, and his share in the political satire of the day is defined and apportioned with as near an approximation to certainty as existing documents will admit. We are glad to see that his biographer still credits him with having "been the first to apply the name John Bull to the English people" and to have drawn "the character which has ever since been accepted as a type of this honest plain dealing fellow, choleric, bold and of a very inconstant temper." This priority would of itself suffice to secure Arbuthnot against oblivion, but his biographer does not fail to adduce his many other more solid claims to the consideration of posterity. He has given us, in short, a masterly, full length portrait of the most learned and most lovable professional man of Queen Anne's and of the following reign, making us understand with all the detail that was accessible the physician "who knew his art but not his trade," the prologiser of lives like Pope's, the wise counsellor in social and professional crises, the friend and the promoter of all science, to which indeed he was himself among the most scholarly and independent contributors.

Having admitted the conspicuous success of the biography we may point out a few shortcomings to be made good in a subsequent edition. We pass over the failure of the author to note from the *Gentleman's Magazine* such curious facts as Arbuthnot's public encounter with the card playing French dog which beat the doctor at quadrille—a specimen of social manners characteristic of the time. We say nothing of his error in making Matthew Prior an Oxford man, though that, in his undoubted familiarity with "the Augustan age of English literature," is not a little surprising. But we think his otherwise complete bibliography unaccountably defective in omitting all mention of Dr B. W. Richardson's memoir of "John Arbuthnot, M.D., F.R.S., the Medical Scholar," published in the *Asclepiad* for the second quarter of 1887. Much that is most valuable in his biography was anticipated in that memorable sketch, to which the reader has still to be referred for an adequate estimate of Arbuthnot's undoubted pre-eminence as a scientific consultant over nearly all his con-

temporaries "Respiration is the second digestion" was one of Arbuthnot's generalisations which of itself, as Dr Richardson eloquently points out, would stamp him as a profound observer of nature, far ahead of his time.

For the remainder of his biographer's work, the carefully edited reprint of Arbuthnot's writings, genuine and doubtful, we have nothing but unqualified praise. These may now be read without the torture inseparable from the loose spelling, the badly accented Greek, the slovenly references, the thousand and one *maculae* which make eighteenth century publications so often an eyesore and a penance. Their intrinsic merits, which even such typographical *deshabille* could never impair, are as fresh to-day as when they first saw the light, and if the reader wants exhilaration of the most genuine and hearty kind, the outcome of a humour second only to that of Cervantes, we could give him no better advice than that so often heard in Queen Anne's day, "Send for Dr Arbuthnot!"

Horses in Accident and Disease By J. ROALFE COX, F.R.C.V.S. Edinburgh David Douglas. 1892.

WHAT might be termed the "physiognomy" of suffering is perhaps better defined in some of the domestic animals than it is in man, as in them there is much less mind and possibly no imagination to confuse or mask the expression of those sensations of discomfort, pain or agony which they experience when labouring under the effects of disease or accident. There is certainly no malingering, no fictitious appearances and no hysterical tendencies such as so often baffle and mislead the physician and surgeon, and though the veterinarian is exposed to the great disadvantage of having to minister to dumb patients who cannot tell him in words what their sensations are, yet, on the other hand and for the same reason, they cannot beguile him by a wrong description or conceal their condition by false statements. To the experienced observer of animals, one who has a natural sympathy with them, they manifest their feelings and desires in a manner which rarely varies to any extent and show in an unmistakable way the character, seat and intensity of the maladies or injuries from which they may be suffering. Nearly every disease has its own special features or symptoms, which reveal its presence and render its diagnosis a matter of little difficulty to those who have been trained and accustomed to deal with disabled animals.

Of all the creatures which come under the observation of the veterinary surgeon it might be asserted that the horse is the one which exhibits the most expression in disease—at least, it is the one which, because of its greater utility and monetary value, has been most closely studied in this respect. Its facial expression, its attitudes and its movements tell their story and inform the observer as unerringly as if the animal were endowed with speech, but this only to the observer who understands and can interpret them. Those who have attempted to describe the symptoms presented by suffering animals have always found great difficulty in doing so satisfactorily, because of the impossibility of grouping them in such a fashion as will present a faithful picture to the mind's eye and enable an untutored person to recognise the ailment treated of, and therefore in some works on diseases of animals attempts have been made to supplement the verbal descriptions by drawings representing the positions and attitudes assumed but at best these have been little better than caricatures. To aid the veterinary student and horse owner in distinguishing between different maladies and mishaps Mr Cox, an able veterinary surgeon of long experience, has published a book in which verbal description is made altogether subordinate to the true delineation of twenty-eight cases of particular diseases and accidents frequently met with. The figures if somewhat roughly are yet strikingly portrayed and in addi-

tion to being fairly well drawn, convey at a glance a capital series of object lessons in clinical veterinary medicine and surgery which cannot fail to be instructive to those for whom they were produced. The sketches of horses suffering from that most painful and serious foot disease, laminitis, from congestion of the lungs, tumour in the brain and luxation of the patella, are excellent for the instruction they afford, but perhaps the most telling is the picture of the horse affected with tetanus, in which we see the characteristic attitude of the limbs, head and tail, but especially the face with its *risus sardonius* and the eye with the *membrana nictitans* protruding over it, giving to the disease such a strange and distressing character in this animal. The book is a novelty in its way, and does Mr Cox much credit as an artist and close observer of equine life.

Treatise on the Diseases of Women for the Use of Students and Practitioners By ALEXANDER J. C. SKENE, M.D. Professor of Gynaecology in the Long Island College Hospital, Brooklyn, New York. Second Edition, Revised and Enlarged. London H. K. Lewis 1892.

ALTHOUGH the number of pages in this edition is almost the same as in the first, the author has managed to incorporate much additional matter by considerably enlarging the size of the page. The new chapters deal with ectopic gestation, diseases and injuries of the ureters, vesical hernia and its surgical treatment, moreover, the author has taken the opportunity of stating his most recent views on laparotomy, ovaritis and injuries of the cervix and pelvic floor.

As the book aims at presenting "the fully matured and essential facts in the science and art of gynaecology," and is intended as a text-book for students, we should not have expected to find such a passage as the following: "The effect of flexion on the uterine canal is to produce constriction or occlusion of the internal os. The stricture thus formed gives rise to accumulation of the secretions of the uterine cavity and to partial retention of the menstrual products. The circulation in the uterus, as will be readily understood, is interfered with. The obstruction tends to keep up congestion, and this may eventually lead to oedema and a predisposition to endometritis and pelvic peritonitis. It would scarcely be possible to find two points as to which there has been more dispute than the relation of uterine flexion, on the one hand, to stricture of the internal os and, on the other, to the circulation through the uterus. The author does not seem to be acquainted with Dr John Williams's well known and convincing paper on the latter of these two questions. So far from the statements in the passage we have quoted being generally accepted as facts, we may say at once that the best English authorities hold that flexion does *not* cause obstruction at the internal os and that it has no effect whatever in producing a state of venous congestion in the uterus.

Again, it seems to us that Dr Skene makes too little allowance for the individual variations in form that should be classed within the limits of normal. For example as regards the projection of the vaginal portion of the cervix if it projects too much we find an operation is recommended to shorten it, and if it projects too little an operation is to be undertaken to lengthen it. Surely it would be as reasonable to set up an exact pattern, for instance for the nose and to operate on all noses that differed from the pattern ideal. We observe that Fig. 64 which inaccurately represented the normal relation of the uterus to the bladder in the first edition, has now been corrected. It is not easy to understand why, in a book consisting of 968 pages and containing 257 engravings the whole subject of malposition of the uterus is dismissed in twenty-three pages and with only one illustration, borrowed from Winchell. It may be doubted whether the author has any personal experience of the supra-vaginal amputation of the cervix, for in the former edition

scribing it we find "The next step is to cut with knife or scissors above the lateral fornices, taking care to avoid wounding the branches of the uterine artery. Thus we see great care must be taken in the preliminary clearing of the cervix", whereas it is of course impossible to free the cervix laterally without cutting branches of the uterine artery, and the consequences must be provided against either by ligatures or pressure forceps. The vagueness of description as to this step of the operation may account for Dr Skene's preference for the galvano cautery rather than the knife, because of "the loss of blood and the uncertainty of manipulation from the hæmorrhage" attending the use of the latter.

About one-third of the book is devoted to a description of "Diseases of the Urinary Organs." The author refers somewhat contemptuously to English literature as containing little information on this subject, we think, however, we could supply a fairly long list of references as to where such information may be obtained. There are numerous illustrative cases scattered throughout the book, amongst the most interesting are those giving a clinical account of some of Dr Keith's hysterectomies for fibroids. We have been unable to find any account of so common an affection as mucous polypus of the uterus, at all events, there is no mention of it in the index. The American system of spelling is of course that adopted throughout the book, we are not quite sure, however, whether or not "sirup" is good American for "syrup."

Les Tumeurs de la Vessie Par J ALBARRAN, Chef de Clinique des Maladies des Voies Urinaires à la Faculté de Médecine de Paris (Hôpital Necker). Préface par le Professeur F GUYON. 73 Figures et 9 Planches. Paris G Steinheil 1892.

THE clinical importance of a careful study of tumours of the bladder has acquired an altogether new importance since they have been brought within the domain of operative surgery. Within the last ten years many valuable works devoted to this subject have appeared, and much has been done to advance our knowledge of the pathology of these tumours and our means of precise diagnosis and satisfactory treatment. No name is more honourably associated with this work than that of Professor Guyon, and any treatise introduced to the profession by a preface from his pen demands attentive study. The book before us is probably the most valuable contribution to this branch of surgery that has yet been made. Dr Albarran is an accomplished histologist and pathologist, and his association with M Guyon for many years has furnished him with a very extensive clinical experience. He has already made more than one valuable contribution to the literature of the surgery of the urinary organs and he has amply demonstrated his fitness to discuss with authority such an important subject as tumours of the bladder. The work opens with a chapter dealing with the history of the subject, and then follows a capital description of the normal mucous membrane of the bladder as shown by the author's own examinations. He affirms the presence of a rich lymphatic network in the submucosa—particularly rich in the trigone—and figures it. The classification of the tumours met with is very elaborate—too minute and particular, perhaps, for clinical purposes. The morbid anatomy is well described, as are also the clinical course and the diagnosis. Dr Albarran lays stress upon the fact that naked eye appearances of a tumour are no safe test of its structure, and also that its minute structure is no criterion of its clinical history. While none of the infiltrating tumours examined by him were benign in character, fully half the pedunculated epithelial tumours were malignant in nature. He points out how long a history some malignant tumours have, and is of opinion that a benign tumour may become malignant and that a cancerous growth may develop in an innocent tumour. The question of treatment is very

fully discussed, and the numerous operations that have been devised for these diseases are carefully described and appraised. While condemning some of the more extensive and hazardous, he advocates a more free and more careful removal of even the simplest pedunculated growths than is usually practised here. Preferring in all cases the supra-pubic route, he has abandoned the forceps recommended by Thompson, and cuts away the tumour with the knife and scissors, being careful to remove all the mucous membrane from which it grows, and in many cases the muscular wall of the bladder itself, and then sutures the edges of this wound in the bladder. He describes and figures some good examples of secondary infection of the bladder by contact with the tumour, and demonstrates also, what has been denied, that secondary deposits may occur in the pelvic lymphatic glands and also in other internal organs. The work closes with a capital table of cases—first those seen and examined by himself, then those recorded by other surgeons. Dr Albarran is very thoroughly acquainted with the literature of the subject and very numerous references to the writings of others are given. He is to be most heartily congratulated on the result of his labours, for he has produced a most admirable and valuable treatise, which is the best work of reference on this subject that has yet been published.

Medical Electricity. A Practical Handbook for Students and Practitioners. By W E STEVENSON, M.D., and H LEWIS JONES, M.A., M.D. London H K Lewis, 1892.

By the early death of Dr Stevenson the science and art of the application of electricity to the diagnosis and treatment of disease lost a foremost exponent, one who had thoroughly mastered the intricacies of the subject and whose writings upon it had already attracted much attention. The present monograph, intended to be, as it will no doubt become, a standard text-book, was planned and commenced by him, and the task of collating the fragmentary portions which he left, and of supplying all that remained to give the work completeness, fell to Dr Lewis Jones. This has involved the contribution by the latter of the major part of the volume, and the manner in which his duty has been performed is worthy of all praise. Unlike many treatises on the subject a large amount of space is devoted to the exposition of the various forms of electricity and its apparatus, and herein we think the authors have done wisely. It is obvious that the student of electricity in relation to physiology and disease ought to start with a clear comprehension of the physical science itself, and it is well not to take for granted a knowledge which may be at the best vague and imperfect, whilst nothing but good can come of a fresh consideration of a branch of physics which formed a part of his elementary education. These matters, too, are treated in a clear and concise manner—statical electricity being first described and then electricity in motion, with valuable explanations of laws and definitions. These chapters are followed by one on the apparatus of statical electricity and the mode of its application, and that by others upon galvanic batteries and accessory apparatus. The preference is given for medical purposes to the Leclanché cell and useful hints are given as to the choice and care of batteries. Indeed the practical character of the book is one of its main and most valuable features. The chapter upon physiology is full of interest, although it demonstrates the comparative obscurity which veils the question of the action of the electric current upon the tissues generally, apart from its special effect on nerve and muscle. There is no doubt that this imperfection in knowledge has done much to propagate erroneous ideas concerning the effects of electrical treatment, and the lack of scientific explanation has given unbounded opportunity for surmise and conjecture. The labours of Professor

Erb have done more than any other work to throw light upon the value and meaning of electricity as an aid to diagnosis, and accordingly in the chapter devoted to this latter subject Erb's methods and conclusions are largely drawn upon. A short chapter on general therapeutics, in which we are glad to note the deprecation of electrical treatment being carried on by the patient himself, and the utility of so-called "electric belts," is followed by one on the electric bath which Dr Stevenson described in the columns of THE LANCET. The precise value of this mode of application of electricity can hardly as yet be estimated, but it is claimed to act beneficially as a tonic, and therefore to be of use in many conditions of purely functional debility, as well as in certain organic states. The treatment of nervous diseases and of other conditions in which galvanism or faradism can be found useful is dealt with more from the published experiences of other writers than from those of the authors. The work concludes with chapters on electrolysis, the galvanic cautery &c. We think the book to be sound in its teaching and practical in execution, and believe it will meet with merited success.

LIBRARY TABLE

The Extra Pharmacopœia By WILLIAM MARTINDALE, F.C.S., and W. WYNN WESTCOTT, M.B. Lond. Seventh Edition. London H. K. Lewis 1892.—Almost before there has been time for a due appreciation of the excellences of the sixth edition of Martindale's "Extra Pharmacopœia" the indefatigable compilers in presenting a seventh edition prove once more the great strides which are being made in pharmacy. Fortunately as the name indicates, a large proportion of the material in this handy book is merely on trial, and will doubtless be condensed or deleted in later editions, otherwise the crowd of new remedies would appear to be overwhelming. Still, new drugs are constantly being recommended, and the advantages of this accumulation of new facts and suggestions are sufficiently appreciated by the medical profession. The new edition is in every respect as reliable as before, and it contains useful references to all newer remedies, indicating not only the most convenient way in which they may be employed, but also the results which have been given in various forms of disease in the hands of different observers. The book is one to which we can extend a cordial welcome and for which a large sphere of usefulness may be predicted.

Diagnosis by the Urine By ALLARD NUMMINGER, M.D. Philadelphia P. Blakiston, Son and Co 1892.—This little work forms one of a large class of manuals for which there always seems to be a demand. It covers nearly all the ground essential to the determination of the characters and composition of the urine for clinical purposes, and is therefore of some utility. The author gives some of his own experiences which will be appreciated—as, for instance, his statement that when the daily quantity of urea falls habitually below twenty grammes in an adult of active pursuits and well nourished body disease of the liver or kidney may be suspected, and of the detection of small quantities of albumen by suddenly plunging the test-tube into cold water after boiling the urine with acid. He only describes the hypobromite method of urea-estimation, advising the urometer devised by Dr Doremus, and does not mention the fermentation test for sugar in the urine. We note also the absence of any reference to Ehrlich's reaction, or to the significance of excess of indica in the urine. The book, too, which is well illustrated, is capable of some expansion without detracting from its utility.

Essentials of Diagnosis By SOLOMON SOLIS COHEN, M.D., and AUGUSTUS A. ESHNER, M.D. Philadelphia W. B. Sanders 1892.—In this work we find the subject of medical diagnosis treated in a novel way—namely, by means of "question and answer." The plan is ingenious and may

be helpful to the student, but we confess we should not care to see it too much extended. The "answers," which, of course, form the bulk of the text, are ample and sufficient, the leading points being clearly and concisely enunciated. After all the plan adopted is only another way of subdividing subjects, a slight departure from the orthodox method of chapters and sections, and the real merit of the book lies in the accuracy of its text.

Eye strain, commonly called Asthenopia By ERNEST CLARKE, M.D. Pp 168, with twenty-two illustrations. London J. & A. Churchill. 1892.—In this little volume Dr Ernest Clarke, without offering to the profession anything absolutely new, has placed the well known features of excessive work of the eyes, especially in the case of patients who are affected with some error of refraction or who suffer from muscular or nervous debility, in a clear and easily intelligible form. The treatise is an expansion of a paper read before the West Kent Medico-Chirurgical Society. Asthenopia, proceeding from overwork and fatigue of the retina, was recognised though not thoroughly understood by Taylor in 1766 and by Scarpa and Beer at the beginning of the present century, whilst Mackenzie dimly perceived that it was sometimes in part dependent upon the exhaustion or imperfect action of the extrinsic muscles of the eye, but the etiology of the affection was not cleared up until the whole subject of refraction had been worked out by Donders, who maintained that in the common form of asthenopia hypermetropia is scarcely ever absent. The finishing touch to our knowledge of the causation of the disease was given by von Graefe, who demonstrated the importance of impairment of the power of convergence in inducing asthenopia and therefore of weakness of the internal recti muscles. Dr Clarke describes in succession the various conditions which may induce eye strain and gives concise but clear accounts of the several subjects of accommodation, hyperopia and myopia. He regards the shadow test as the best method for diagnosing astigmatism. He accepts Foster's statement that the primary position of the eyes is that which is assumed when, with the head erect and vertical, we look straight forward to the distant horizon. There seem to be good reasons, however, for thinking that the eyes are really at rest when they fix a distant object about 15° below the plane of the horizon. Their visual axes are then probably parallel or nearly so. The section on muscular insufficiency gives the details of the various methods in use for determining the amount of the insufficiency and of treating that condition. He comments on the extraordinary frequency with which tenotomy is performed in America, one practitioner having operated no less than 2000 times. Well may he call it "tenotomy mania." The final chapter is devoted to Retinal Asthenopia. This little monograph upon an important subject has been well thought out and well written by the author.

A New Pronouncing Dictionary of Medicine being a Volu minous and Exhaustive Handbook of Medicine and Scientific Terminology, with Phonetic Pronunciation, Accentuation, Etymology &c By JOHN M. KEATING, M.D., LL.D., and HENRY HAMILTON, with the collaboration of J. CHALMERS DA COSTA, M.D., and F. A. PACKARD, M.D. With an Appendix. Pp 818. Edinburgh and London Young & Pentland 1892.—The nature and scope of this work are pretty well defined by its title. In addition, however, to the features enumerated above there are a table of medical abbreviations, which is indeed common to other medical dictionaries, and a table of suffixes and prefixes, which, so far as we are aware, is not included in other books of this class. The appendix is pretty full and will be found of great use for purposes of reference. It gives tables of weights and measures, a table for calculating the period of utero gestation and another of equivalents of centigrade and thermometric scales, pictorial illustrations of diameters of the foetal head, a chart

scribing it we find "The next step is to cut with knife or scissors above the lateral fornices, taking care to avoid wounding the branches of the uterine artery. Thus we see great care must be taken in the preliminary clearing of the cervix", whereas it is of course impossible to free the cervix laterally without cutting branches of the uterine artery, and the consequences must be provided against either by ligatures or pressure forceps. The vagueness of description as to this step of the operation may account for Dr Skene's preference for the galvano cautery rather than the knife, because of "the loss of blood and the uncertainty of manipulation from the hæmorrhage" attending the use of the latter.

About one-third of the book is devoted to a description of "Diseases of the Urinary Organs." The author refers somewhat contemptuously to English literature as containing little information on this subject, we think, however, we could supply a fairly long list of references as to where such information may be obtained. There are numerous illustrative cases scattered throughout the book, amongst the most interesting are those giving a clinical account of some of Dr Keith's hysterectomies for fibroids. We have been unable to find any account of so common an affection as mucous polypus of the uterus, at all events, there is no mention of it in the index. The American system of spelling is of course that adopted throughout the book, we are not quite sure, however, whether or not "syrup" is good American for "syrup."

Les Tumeurs de la Vessie Par J. ALBARRAN, Chef de Clinique des Maladies des Voies Urinaires à la Faculté de Médecine de Paris (Hôpital Necker). Préface par le Professeur F. GUYON. 73 Figures et 9 Planches. Paris G Steinheil 1892.

THE clinical importance of a careful study of tumours of the bladder has acquired an altogether new importance since they have been brought within the domain of operative surgery. Within the last ten years many valuable works devoted to this subject have appeared, and much has been done to advance our knowledge of the pathology of these tumours and our means of precise diagnosis and satisfactory treatment. No name is more honourably associated with this work than that of Professor Guyon, and any treatise introduced to the profession by a preface from his pen demands attentive study. The book before us is probably the most valuable contribution to this branch of surgery that has yet been made. Dr Albarran is an accomplished histologist and pathologist, and his association with M. Guyon for many years has furnished him with a very extensive clinical experience. He has already made more than one valuable contribution to the literature of the surgery of the urinary organs and he has amply demonstrated his fitness to discuss with authority such an important subject as tumours of the bladder. The work opens with a chapter dealing with the history of the subject, and then follows a capital description of the normal mucous membrane of the bladder as shown by the author's own examinations. He affirms the presence of a rich lymphatic network in the submucosa—particularly rich in the trigone—and figures it. The classification of the tumours met with is very elaborate—too minute and particular, perhaps, for clinical purposes. The morbid anatomy is well described, as are also the clinical course and the diagnosis. Dr Albarran lays stress upon the fact that naked eye appearances of a tumour are no safe test of its structure, and also that its minute structure is no criterion of its clinical history. While none of the infiltrating tumours examined by him were benign in character, fully half the pedunculated epithelial tumours were malignant in nature. He points out how long a history some malignant tumours have, and is of opinion that a benign tumour may become malignant and that a cancerous growth may develop in an innocent tumour. The question of treatment is very

fully discussed, and the numerous operations that have been devised for these diseases are carefully described and appraised. While condemning some of the more extensive and hazardous, he advocates a more free and more careful removal of even the simplest pedunculated growths than is usually practised here. Preferring in all cases the supra pubic route, he has abandoned the forceps recommended by Thompson, and cuts away the tumour with the knife and scissors, being careful to remove all the mucous membrane from which it grows, and in many cases the muscular wall of the bladder itself, and then sutures the edges of this wound in the bladder. He describes and figures some good examples of secondary infection of the bladder by contact with the tumour, and demonstrates also, what has been denied, that secondary deposits may occur in the pelvic lymphatic glands and also in other internal organs. The work closes with a capital table of cases—first those seen and examined by himself, then those recorded by other surgeons. Dr Albarran is very thoroughly acquainted with the literature of the subject and very numerous references to the writings of others are given. He is to be most heartily congratulated on the result of his labours for he has produced a most admirable and valuable treatise, which is the best work of reference on this subject that has yet been published.

Medical Electricity A Practical Handbook for Students and Practitioners. By W. E. STEVENSON, M.D., and H. LEWIS JONES, M.A., M.D. London H. K. Lewis, 1892.

By the early death of Dr Stevenson the science and art of the application of electricity to the diagnosis and treatment of disease lost a foremost exponent, one who had thoroughly mastered the intricacies of the subject and whose writings upon it had already attracted much attention. The present monograph, intended to be, as it will no doubt become, a standard text-book, was planned and commenced by him, and the task of collating the fragmentary portions which he left, and of supplying all that remained to give the work completeness, fell to Dr Lewis Jones. This has involved the contribution by the latter of the major part of the volume, and the manner in which his duty has been performed is worthy of all praise. Unlike many treatises on the subject a large amount of space is devoted to the exposition of the various forms of electricity and its apparatus, and herein we think the authors have done wisely. It is obvious that the student of electricity in relation to physiology and disease ought to start with a clear comprehension of the physical science itself, and it is well not to take for granted a knowledge which may be at the best vague and imperfect, whilst nothing but good can come of a fresh consideration of a branch of physics which formed a part of his elementary education. These matters, too, are treated in a clear and concise manner—statical electricity being first described and then electricity in motion, with valuable explanations of laws and definitions. These chapters are followed by one on the apparatus of statical electricity and the mode of its application, and that by others upon galvanic batteries and accessory apparatus. The preference is given for medical purposes to the Leclanché cell and useful hints are given as to the choice and care of batteries. Indeed, the practical character of the book is one of its main and most valuable features. The chapter upon physiology is full of interest, although it demonstrates the comparative obscurity which veils the question of the action of the electric current upon the tissues generally, apart from its special effect on nerve and muscle. There is no doubt that this imperfection in knowledge has done much to propagate erroneous ideas concerning the effects of electrical treatment, and the lack of scientific explanation has given unbounded opportunity for surmise and conjecture. The labours of Professor

ductory remarks on cases to the writer of the notes and not to our own editorial department

The Satellite, a monthly review of the progress of practical medicine throughout the world, as presented in the reports of the corresponding staff of the "Annual of the Universal Medical Sciences" and in the medical press at large, is edited by Dr Sajous with Dr Witherstone as associate editor. It is unnecessary to do more than draw attention to the publication, its scope and usefulness being indicated by the above statement. Being published monthly it is possible for the practitioner to keep himself more easily abreast with the progress made in various branches of the profession abroad than could be done by a perusal of the Annual only, and he obtains this information at an earlier date. Being produced with the advantages named its good quality is guaranteed and a perusal of the numbers which have already appeared enables us to add our testimony to the favourable opinion of others with regard to it.

The Quarterly Journal of Microscopical Science No 133 Vol XXXIV Part I August, 1892—This part only contains two memoirs. The first, a very full and complete account of the Anatomy of *Pentastomum Teretiusculum Baird*, by W Baldwin Spencer of Melbourne University, and the second on the Minute Structure of the Gills of *Talmonetes varians*, by Edgar J Allen of University College, London. The former paper is illustrated with nine carefully drawn plates containing many figures, and the latter with one plate.

Analytical Records

FROM

THE LANCET LABORATORY

[In consequence of the great increase of work which has devolved on the analytical department during recent years it was last year decided to have an entirely new laboratory constructed. This has been done, and an excellent laboratory, built on lines which a long experience with general chemical investigation has suggested as best, now occupies a part of THE LANCET premises so that the work carried on there is under direct editorial supervision. The laboratory, which is divided into two rooms, has been planned of course to meet the special requirements of THE LANCET. Thus it has been provided with all modern apparatus and fittings especially adapted for carrying on sanitary inquiries, the analysis of beverages, foods, drugs, water and gases &c. It is particularly well lighted and ventilated, being situated on the top floor. The benches are amply supplied with gas, water and waste fittings, while here and there taps are provided by which air may be withdrawn from any part of the laboratory by means of a powerful water pump. The balance by Oertling is the newest pattern of short beam, with agate knife edges and planes, rider slide and plate-glass sole, it turns with $\frac{1}{10}$ gr and carries 5000 gr. The weights are coated with platinum to ensure constancy of weight, they are thus protected from the oxidising action of the air and the attack of acid vapours. The large spectroscope and the pocket spectroscope are by Browning, and the microscope by Zeiss is provided with Zeiss's polariscope attachment. For the analysis of gases Hempel's improved apparatus has been adopted, while the newest form of Sprengel mercury pump has been procured for the production of vacua. A Gay Lussac barometer is employed for the measurement of pressure. The fume chamber is situated in a remote corner of the room and is provided with a ventilating shaft, whilst the gas-supply may be regulated from without so that the doors of the chamber need not be opened when the burners require to be adjusted. For the analysis of organic substances in

which combustion is involved Fletcher's convenient furnace is employed, while for glass blowing &c. the same maker's blowpipe and bellows have been obtained. The shelves carrying the reagents can be adjusted to the height of the bottles to be used in any particular analysis in process of examination. The inner room is set apart for literary work and is provided with bookcases containing the latest editions of the literature of chemical science. By taking these steps, which have involved considerable outlay, we hope to continue with even greater accuracy, care and assiduity, those investigations which have always been so marked a feature of the work of THE LANCET.]

VARIOUS TOILET PREPARATIONS

(NAPOLEON PRICE AND CO, PROPRIETORS OF THE ROYAL PERFUMERY CO DEPOTS 27, OLD BOND STREET, W, 161, ALDERSGATE STREET, E.C.)

The progress that has been made during the last decade in the art of soap making and in the making of other articles of the toilet is certainly remarkable. Soaps in times gone by were more or less the products of a haphazard formula, of which not infrequently substances other than alkali and fat, and oftentimes of an injurious nature, formed a part. Now, on the contrary, it is the aim—certainly of manufacturers of repute—to produce a soap as nearly chemically pure as manufacturing on a large scale will permit. Indeed, so admirably prepared are many soaps that they may be regarded as the pure salts—oleates, pelmitates or stearates—of sodium. The soaps of the above firm give evidence of this, for according to analysis the ingredients are excellently balanced, they are practically free from moisture, and contain but the merest traces of those agents which are necessarily introduced in the course of manufacture. The soap, not inaptly called Velveen and also Twentieth Century Toilet Soap, is of especial excellence. It is delicately scented and evidently made from the best materials. On analysis it was found to contain 8.61 per cent moisture and 9.50 per cent combined alkali (Na_2O). Edelweiss soap, which, as its name implies, is made fragrant with excellent Edelweiss perfume, is another admirable specimen of manufacture. It contains still less moisture—6.65 per cent—while the combined alkali amounted to 9.97 per cent. In brown Windsor soap the moisture amounted to 10.24 per cent, and the combined alkali to 9.30 per cent. It is well suited for ordinary use. Baby soap was perfectly free from alkali, the combined Na_2O amounting to 9.97 per cent and the moisture to 9.03 per cent. The Glycerine and Cucumber soap was equally satisfactory, the combined alkali amounted to 9.60 per cent, and the moisture to exactly 10 per cent., while the green colouring was ascertained to be of a perfectly harmless nature. Eucalyptus and Pine Oil soap affords an example of a very superior antiseptic soap. Other soaps examined were as follows. Coal tar soap, improved carbolic soap and a stick of shaving soap. The coal tar specimen responded feebly to the test for free alkali, but the shaving soap, like the rest, was remarkably free from impurity. The following articles of the toilet were also examined: the Edelweiss toilet powder, the nursery and toilet powder, the Edelweiss tooth paste, cherry tooth paste, a golden oil for the hair, as well as the under-mentioned perfumes. Edelweiss bean ideal perfumes, concentrated essence of Spinarosa (a new perfume from Guatemala, where the flower has grown unnoticed for years) and a perfume styled Gloriosa. The tooth pastes are very agreeable in the mouth, are antacid and antiseptic and contain perfectly harmless ingredients. The Edelweiss toilet powder is fragrant with perfume and was found to be composed of a certain starch, together with exceedingly finely pulverised chalk and a micaceous substance. The nursery toilet powder contained only comminuted starch, delicately scented. The golden oil is an attractive looking pomatum which is solid at ordinary temperatures, but which melts to a clear amber oil on warming. The oil did not appear to saponify when

depicting nerve distribution &c, characteristics of bacteria, pharmacological data, lists of incompatibles and of poisons, diagrams of motor points, synonyms of disease &c., formulæ of solutions in common use, and some other matters. This dictionary, though not of course pretending to compete with Billings' work or with Foster's "Illustrated Encyclopædic Dictionary," is, on account of its convenient size and the clearness of its typography, to say nothing of the value of the appendix, likely to meet with great favour. We have not gone into a critical examination of the book, but are glad to welcome its appearance on account of its distinctive features and its handy and presentable form.

Domestic Electric Lighting treated from the Consumers' Point of View By ED C DE SEGUNDO, Assoc M Inst C E London H Albaster, Gatehouse and Co, 22, Paternoster row, E C.—In this interesting brochure the author endeavours to clear up some of the elementary difficulties with regard to electric lighting. He shows that, economically considered, electricity compares favourably with gas and oil, and he gives some valuable information about wiring and insulating wires without recommending any particular method, however, although the expense of several of them, with notes on their respective advantages and disadvantages, is discussed. Public interest was considerably spurred in this direction by the domestic department of the Electrical Exhibition at the Crystal Palace, but sparse attention was paid to the details and mode of lighting. The book should serve as a useful guide to any who intend to use electric light for domestic purposes and it may help to clear up many hazy ideas on this interesting branch of the subject.

Civilisation and Progress By JOHN BEATTIE CROZIER Third Edition. London Longmans, Green and Co 1892.—The third edition of this work has now been issued, revised and enlarged, after being out of print for the last three years through "various hindrances," as its author tells us in his preface, and "in the face of a steadily increasing public demand," which we can well believe. The book deals with subjects of perennial interest in an original and attractive way, and is written in a fluent metaphorical style that catches the attention and keeps it fixed, it bears, moreover, the impress of conviction. In his preface to the second edition, which appeared in 1888, the author answers some of his critics, and in revising the present issue he has more fully attempted to meet their objections. The alterations and additions, which are not numerous, comprise the substitution of fresh titles to a few chapters and the introduction of some explanatory passages in the text, notably a section on Hegel's "Philosophy of History" towards the end of the book, and another near the beginning entering more fully into "the New Organon," or method employed to investigate and, as the author believes, to solve the problem involved in the complex phenomena of civilisation and progress. The field covered is extensive—practically exhaustive—and the reader is carried swiftly from Tradition to the Future in seven league strides. The chapter devoted to Cardinal Newman and to some of the fallacies of his teaching is especially interesting, as also are those which deal with vigour and directness with the systems of such men as Bacon, Carlyle, Comte, Emerson and Herbert Spencer, and the merits of the New Organon are set forth with such entire confidence that the author's system is at least deserving of examination and his book of the attention which it compels.

Scenes in Fairyland By Canon ATKINSON London Macmillan and Co 1892.—*The Girls and I a Veracious History* By Mrs MOLESWORTH London Macmillan and Co 1892.—Amongst the publications which fill the book sellers' shops at Christmas time those intended for children occupy a large space. Indeed it is a striking fact that the amount and quality of children's "light literature" are year by year increasing. To be sure no modern book will detract

from the interest of Andersen and Grimm, and we would not venture to compare Canon Atkinson's contribution to fairy lore with stories from their imitable pens. Still the author of "Forty Years in a Moorland Parish" never writes without telling something worth hearing, and in the extravagances of imagination permitted to the writer of fairy tales he is just as charming as in his description of existence in a country village. The other little book, by a well-known writer for children, is a simple but well told story, very natural and very homely and healthy.

The Veterinary Journal London Baillière, Tindall and Cox.—The numbers of this monthly periodical for November and December contain much interesting matter, in addition to reports of veterinary associations and valuable extracts and précis of articles from German, French and Italian journals relating to animal medicine and surgery. Among the more important original communications the numbers contain are one on the diagnosis of glanders by the hypodermic injection of mallein from the pen of Professor Déguve, director of the Brussels Veterinary School, in which the great value of that agent is again clearly demonstrated, an interesting case of intestinal obstruction in a mare due to a large ovarian cyst, an account of an outbreak of epizootic abortion among cattle in Australia, an instructive paper on the use of anaesthetics for diagnostic purposes, another on hepatic apoplexy in horses, a suggestive article on septic pleuro pneumonia in calves, by Professor Liennaux, and an exceedingly important description of the "maladie du coit" (recently noticed in a special article in THE LANCET) as it is observed in the United States, into which the disease has been imported from France. This communication is from the pathological laboratory of the University of Nebraska, and the reporter states that there is much reason for believing that the bacterium giving rise to the disease has been at last discovered. This journal continues to give very satisfactory evidence of the steady progress veterinary science and art are making at home and abroad.

Annual of the Universal Medical Sciences A Yearly Report of the Progress of the General Sanitary Sciences throughout the World Edited by CHARLES E SAJOUS, M D, and seventy Associate Editors, assisted by over two hundred Corresponding Editors, Collaborators and Correspondents. Illustrated with Chromo lithographs, Engravings and Maps. The J. A Davis Company, Publishers, Philadelphia, New York, Chicago and London 1892.—Our readers are already familiar, from our notices of previous editions of this valuable series, with its general scope and great utility. The fact that there are so many medical men of standing engaged in the production of the work is a sufficient guarantee for the excellence of it, and this, the fifth series, does not suffer from a comparison with its predecessors. Although there are few changes, and none of much importance, in the arrangement of the facts culled from so many sources and presented in a readable form to the profession, they are all in the direction of improvement. "The Annual by no means pretends to have reached the point of excellence that it is hoped it will some day attain. A conscientious attempt to make it advance as rapidly as possible has been made, but many are the shortcomings still to be conquered and the developments still to be evolved." But few changes have been made in the associate staff. Dr Joseph O'Dwyer has undertaken the department of "intubation" and Dr Baruch that of "climatology and balneology," to which has been added a section of "hydrotherapy." Dr Witherstone no longer prepares the index, a very laborious work, there being a separate index to each of the five volumes, the one at the end of the fifth volume being a general one, but this is undertaken by Dr Kyle and Miss N I McCarthy. The references to contributions printed in THE LANCET are numerous. In mentioning cases from the "Mirror of Hospital Practice," however, a mistake is frequently made in attributing the intro-

stitute. It resembles pepsin powder in appearance, burns with a disagreeable smell and leaves little or no residue. No evidence of its digestive action on coagulated albumen was gained, but it was found to convert starch very readily. The Cascara Sagrada preparation is a fluid extract containing alcohol. It is a dark brown clear liquid, slightly acid to test paper, turning turbid when treated with water and clearing again on addition of alkali. It is evidently not lacking in the active ingredients of the "sacred bark."

BYNO HYPOPHOSPHITES.

(ALLEN AND HANBURY, FLOUGH COURT, LOMBARD STREET, E.C.)

This is an excellent preparation in which are ingeniously combined the hypophosphites of iron, lime, potash and manganese, with the alkaloids of nux vomica in combination with the well known active malt essence, bynin, of the same firm. We have proved its efficacy as regards digestive power, while the tonic salts already indicated and the alkaloids of nux vomica were readily detected. The ash contained an abundance of phosphates, part of which are of course derived from the hypophosphites originally present. Putting on one side its undoubted therapeutic value, attributable to the hypophosphites, the liquid malt itself not only affords an excellent vehicle in the place of ordinary syrup, but it obviously increases this value by reason of its digestive action.

FIRE BRIQUETTES.

(CARVILLE CHEMICAL COMPANY, LIMITED, PAISLEY)

These are composed of a resinous inflammable material worked into briquettes with sawdust. They readily ignite and remain incandescent for some time after the more combustible constituents are exhausted. Although they are more convenient to use than ordinary firewood, they are decidedly slower in producing a well lighted fire, and the material is of such a nature that, like turpentine and camphor it burns with intensely sooty flame. This is a drawback, perchance a trifling one, but the less smoke there is produced the better, whether it is from the fuel with which the fire is lighted or from that which serves afterwards to keep up the fire.

ALBION MILK AND SULPHUR SOAP

(THE ALBION SANITARY SOAP CO 78, NEW OXFORD-STREET W.C.)

In one respect only are we able to speak favourably of this soap. It is beautifully white, as white as any similar preparation we have seen, but in regard to its claim to the title of "sulphur soap" we are doubtful. In the specimen submitted we failed to recognise sulphur in any form that could be regarded as of "sanitary" value. Moreover, it contains free alkali and this fact is calculated to make itself evident to tender and delicate skins.

BRAND AND CO'S MEAT JUICE

(BRAND AND CO 11, LITTLE STANHOPE STREET MAYFAIR, W.)

This is a powerful, nourishing and stimulating fluid, obtained from prime beef by submitting it to pressure in the cold—a method of preparation which must be regarded as highly satisfactory, for, according to our analysis, the valuable principles of the meat have not only been preserved intact, but the fresh, agreeable and natural flavour of beef has also been retained. On warming it turns quite solid from the presence of unaltered albumen. When spectroscopically examined the characteristic hæmoglobin absorption bands are observed, but, after boiling, the clear liquid no longer exhibits this property, while the coagulum assumes a dark-red colour. Analysis gave the following results. Water, 60.00 per cent., beef extractives, 29.65 per cent. (containing 3.06 parts of nitrogen), and mineral matter 10.35 per cent. consisting chiefly of soluble phosphates and common salt. No objectionable preservatives were detected. The alimentary value of the preparation is evident.

New Inventions.

FURTHER IMPROVEMENTS IN INHALERS FOR FACILITATING SAFE ADMINISTRATION OF CHLOROFORM OR METHYLENE

THE well known feather serving as a respiration indicator in the inhalers which were described in THE LANCET of April 17th, 1891, was originally made to rise by expiration to an angle of 90°. Messrs Krohne and Sesemann now put a check in the axis, into which the feather is fixed, which prevents it from rising above an angle of 50° or 55°, which permits a more accurate estimation of the strength and character of the respiration. They also make a number of perforations around the rim of the inner cone of their inhalers upon which the feather falls at inspiration, by which it is made more certain that free respiration is not interfered with. They also make a chloroform bottle, as shown in the engraving, in which they combine both the improvements suggested by Dr W Dudley Buxton and Mr C Brann—viz., the addition of a funnel for facilitating refilling during a prolonged operation and an arrangement of their own for preventing the injection of fluid chloroform or methylene by accidental over tilting or turning the bottle upside down. It is of a size a trifle larger than the ordinary Junker's. They also introduce a new device of their invention for watching the respiration by hearing. A double tube is made for use in operations on the mouth, nose or face. Through one of the tubes the narcotic vapour is administered in the usual way, whilst the second tube is brought in direct communication with one or both ears of the administrator in the manner of a single or double flexible stethoscope, enabling him to watch and estimate the respiration by the corresponding sound conveyed to the tympanum. They have also adapted the hearing tube to their plain open-ended cone, by means of which the respiration can be watched during every stage of the administration and, if desired, by several observers at the same time.

Through one of the tubes the narcotic vapour is administered in the usual way, whilst the second tube is brought in direct communication with one or both ears of the administrator in the manner of a single or double flexible stethoscope, enabling him to watch and estimate the respiration by the corresponding sound conveyed to the tympanum. They have also adapted the hearing tube to their plain open-ended cone, by means of which the respiration can be watched during every stage of the administration and, if desired, by several observers at the same time.

AN OPHTHALMIC ATLAS FOR RECORDING PATHOLOGICAL CONDITIONS OF THE FUNDUS BY MEANS OF SUPERIMPOSED LAYERS OF COLOUR

THIS little atlas, which has been devised by Mr Frank Haydon and which is only about three inches and a half square and therefore is easily carried in the pocket, will, we think, prove of great utility in the out-patient room and in the wards of a hospital. It consists of a series of plates exhibiting the fundus of the eye and optic disc printed in vermilion similar to those published in 1886 by Dr Haab, but differing from them in the circumstance that beneath the vermilion is a layer of black pigment, representing the choroid, whilst beneath the black is a layer of enamel white. In some of the plates the usual arrangement of the retinal vessels is inserted, others present the disc only on a red ground, the vessels being omitted. The advantage of the triple layer of colour is that by gently scraping away the red superficial layer with a penknife the black layer is brought into view, whilst by scraping the black away the white enamel representing the sclerotic is exposed. Pathological appearances can thus be roughly but easily rendered and much time saved, for it is difficult, as all know who have tried it, to make a good surface with vermilion and the introduction of the disc and vessels is troublesome on the damp colour. Five minutes' work with a knife will serve to fix the condition of the fundus that would otherwise be lost. The atlas is made by Messrs Down Brothers, St Thomas street.

treated with alkali, it is therefore not liable to become rancid or undergo any undesirable change on exposure to air. Each of the perfumes yielded milky fluids when diluted with water, owing to separation of essential oils, and undoubtedly derived from their respective flowers, and on adding ether the milkiness at once disappeared. As already indicated and subsequently confirmed by analysis, the toilet preparations of this firm afford excellent types of the state of perfection to which the manufacture of soap and similar articles has been brought.

LIQ. COLCHICINÆ SALICYL.
(HOPKINSON AND CO., NOTTINGHAM.)

A dark brown acid solution with bitter saline taste. On adding sulphuric acid it turns solid from separation of salicylic acid, which dissolved in ether and yielded a violet colouration with iron perchloride. Benzene extracted from the liquid made alkaline with soda, the alkaloid colchicine, which was recognised by the yellow reaction it gave with both acids and alkalis. The vapour of alcohol obtained on boiling the liquid ignited with a blue flame, tinged now and again with red, which when viewed with the spectroscope proved to be due to lithium. It further contains cnicifuga.

LIEBIG'S EXTRACT OF MUTTON.
(R. W. ANDERSON, 92, UPPER THAMES-STREET, E.C.)

In spite of the process through which this preparation must have gone in order to obtain so excellent a degree of concentration it forms a very palatable broth when simply dissolved in warm water, although obviously the flavour is considerably improved by the addition of fresh vegetables. It is eminently rich in the extractives of mutton, as may be gathered from the following analysis. Moisture, 11.60 per cent., mineral solids, 21.74 per cent. (phosphate and common salt), meat extractives, 66.66 per cent., containing as much as 10.03 parts of nitrogen. It is perfectly devoid of fat and is therefore suited to feeble digestions and to invalids who cannot partake of ordinary mutton broth. Whilst doubtless it possesses restorative properties in that it contains creatin and other valuable nitrogenous extractives of mutton, and is on this score admirably fitted as an adjunct to soups and other food preparations, it cannot be regarded as possessing *per se* any real nutritive value, because it is necessarily free from albumen and fibre. We note with satisfaction the absence of injurious preservatives.

PALATABLE COD LIVER OIL.
(T. CHRISTY AND CO., 25, LIME STREET, E.C.)

This is a clear golden yellow oil in which the taste of the cod liver oil is well nigh masked by the flavour of cinnamon and some sweetening agent. Hot water dissolves out the sweetness which suggests glycerine or saccharine as a derivative. On stirring the oil with strong sulphuric acid the well known crimson reaction was obtained. To our palate the taste is not disagreeable and those persons to whom other forms have proved repugnant should try this preparation.

SHUTTLEWORTH'S COCOA ESSENCE.
(W. S. SHUTTLEWORTH AND CO., 34, FENCHURCH STREET, E.C.)

Free from husk, readily miscible with hot water and containing a comparatively small proportion of fat—are our analytical notes respecting this specimen of cocoa. Raw cocoa contains, as we have before pointed out, as much as one half of its weight of indigestible fat, and its removal not only eliminates an objectionable ingredient, but its value is thereby enriched because the nitrogenous and stimulating principles are simultaneously concentrated. The above cocoa has been prepared on these lines and its genuine nature is indicated in the following analysis.—Moisture, 5.01 per cent., fat, 15.60 per cent., ash, 4.61 per cent., alkalinity of soluble ash, 0.60 per cent., calculated as Na_2CO_3 . More than two-

thirds of the fat have been skilfully abstracted, in spite of which the flavour of the final product or its infusion is all that can be desired.

DR. THEINHARDT'S FOOD FOR INFANTS AND HYGIAMA FOOD.
(AGENTS SORESENSEN AND CO., 33, GREAT TOWER STREET, E.C.)

So favourable was the first impression conveyed to us on a mere inspection of these foods that we submitted them to careful examination and a somewhat extended analysis. They are both rich in carbo-hydrates, the greater proportion of which is soluble. The food for infants contains less nitrogen than the food called hygiama, while the latter possesses a pleasant milk like cocoa flavour (owing to the cocoa it contains) and the former a very agreeable taste resembling malted milk. Valuable mineral constituents, the phosphates of lime and potash, occur to a remarkable extent in both preparations. Analysis gave the following results.—Hygiama: moisture, 3.41 per cent., fat, 5.01 per cent., ash, 3.81 per cent., nitrogen, 3.65 per cent., carbo-hydrates (chiefly soluble), 64.77 per cent. Infants' food: moisture, 8.00 per cent., fat, 0.5 per cent., ash, 2.76 per cent., nitrogen, 2.2 per cent., carbo-hydrates (mainly soluble), 74.78 per cent. Under the microscope there were indications of the foods having been partially digested, unchanged starch cells were scarce, while dextrin and sugar were present in abundance. These foods are doubtless of high dietetic value, and the ingredients of which they are composed are evidently derived from the best of materials. In addition the flavour of each is very pleasant and calculated to stimulate even a feeble appetite. They are well suited for invalids and infants or for general use. Whilst admitting in the face of our analyses the excellence of these foods, the fact of the name of a medical man being attached to them calls, we think, for adverse criticism.

NUTRIENT WINE OF BEEF PEPTONE.
(ARMOUR AND CO., CHICAGO AND 59 AND 60 TOOLEY STREET, S.E.)

It is well known that peptones are precipitated by strong alcohol, but in the above preparation, in which an excellent sherry is the vehicle, the alcohol, while it is not in sufficient quantity to render the peptones insoluble, tends in all probability to preserve the peptones from objectionable putrefactive change. That true peptone was present was evident from the tests we made, thus with a few drops of copper sulphate and an excess of caustic soda a rose-red colour was produced. Phosphotungstic acid, again, gave an abundant precipitate, as did also saturated ammonium sulphate. When evaporated to dryness the residue amounted to 27.42 per cent., of which 0.87 part was nitrogen and 1.82 parts mineral matter (chiefly phosphate of potassium and chlorides). It is a restorative and nutrient wine of distinct value and its employment in some cases would be preferable to the ordinary beef wine, inasmuch as the nutrient material in it is presented in a predigested state. The taste is satisfactory. Each fluid ounce is stated to contain the nutritious constituents of one ounce of prime lean beef.

BROMO-SODA INGLUVIN AND FLUID EXTRACT OF CASCARA SAGRADA.

(WARNER AND CO., PHILADELPHIA, AND F. NEWBURY AND SONS, 1 AND 3, KING EDWARD STREET, E.C.)

Bromo soda is a skilfully prepared granulated salt containing as active ingredients caffeine one grain and sodium bromide thirty grains. The caffeine can be liberated with an alkali extracted with chloroform and recognised by its very characteristic appearance and chemical tests. It is an agreeable effervescent saline and under the guidance of a physician may be administered with advantage in headache, over-exertion and depression. Inglavin is obtained from the crop of the domestic fowl and may be regarded as a pepsin sub-

THE LANCET.

LONDON SATURDAY, JANUARY 7, 1893

WHEN commencing our first volume for 1892 we reminded our readers that THE LANCET then entered upon the seventieth year of its career, in which confession it might seem to be implied that at the present date the part which we aspire to play must be so well defined that, save for the purpose of private and personal improvement, there could be no object in our reviewing it. But upon the view which we have always taken of our relation to our readers that is not the case. We do not write merely to be read but also for the purpose of giving expression to the feeling of the great profession which we represent upon the various questions which from time to time it is our duty to discuss and of putting that expression of feeling upon record. In such a task the whole profession is concerned with us and therefore it is fitting that we should from time to time submit to our professional brethren an account of the way in which our work has been discharged. That their interest in this work is both real and keen is abundantly evidenced not only by the continued growth of our subscription list but also by the contents of our "Correspondence" columns, which are remarkable not more for the variety of the topics therein treated of than for the number of correspondents who contribute and the extent of their communications. This, which is a feature of THE LANCET upon which the Editors put the very highest value, is, moreover, a feature which in recent years has undergone a great development. A reference to one of our past volumes, though of recent date will make good this assertion. For example, in 1889 the "Correspondence" columns occupied 130 pages, whereas last year they extended to 267 pages. It is hardly necessary to add that in such a mass of correspondence no single topic of interest to the profession was lost sight of, and it would hardly be too much to allege that every phase of opinion held upon debated subjects of this order found some fitting expression.

It is not in this branch only of our work that the growth of the past year has been marked. Indeed, it is interesting to note how in various branches the volume of our work expands by a sort of natural growth, corresponding in this respect to the development of the studies with which our profession is identified. If a sufficiently long period of time—say, a decade or the quarter of a century—is passed in review it is easy to discern that events are marching in ordered sequence and with a rapid step. But like the travel of the shadow on the dial the movement is in general too imperceptible for direct observation. Epochs or epoch making events must be used as dividing lines to mark the hours and register the movement if this is to be made sensible and amenable to observation. So everybody is able to discern the growth by which our art becomes more precise and our science more profound. But in a more subtle way this process may be traced in the increase registered from year to year in the various departments of our work. Every new view of the old facts brings some new facts into light and every new fact registered leads sooner or later

to the enlargement of our theoretical comprehension of both old and new. Thus on both sides the field of our labour is ever increasing and this growth is most graphically shown by the increased demands which year by year are made upon our space. Under this view the following statistics of our publication during 1892 will be of interest. During 1892 one number extended to 216 pages, one to 200 pages, one to 168, two to 152, nine to 144, twenty five to 136 and twelve to 128 pages. Only in one issue was the theoretical limit of 120 observed. Altogether the two volumes of THE LANCET for 1892 contain 7392 pages, an average of 142 pages for each issue, an increase of five pages per number over the average numbers of 1891. Not only has the work of composing and publishing to be transacted at the office of the paper, but for the more convenient and efficient accomplishment of the work of analysis, of which the results are regularly laid before our readers, a chemical laboratory has been fitted up upon the premises in which this work is carried on.

Turning from these general aspects of our work we may allude briefly to some special departments in which noteworthy results have to be recorded. And here we must devote a line to the mention of the Metropolitan Hospital Sunday Fund collection which has always engaged the special interest of our readers. That interest received an eminently practical expression when in 1891 in response to an appeal made in these columns the medical practitioners of London circulated among their patients some forty thousand copies of the special Supplement of THE LANCET prepared and issued in support of that collection. A similar suggestion elicited a like response from our readers last year, and we doubt not that the personal interest which they have thus shown has had a very substantial effect upon the success of the appeal made to the religious congregations of the metropolis. It is indeed true that we are not able this year as we were last to point to some one munificent gift as having been secured by the agency of THE LANCET Supplement, but that could not be expected. With the aid of our readers and of the various ministers of religion and their coadjutors we were enabled to circulate one hundred and forty thousand copies of the reprinted Supplement, and we are well satisfied that the wide diffusion of a knowledge of the facts of the case thus brought about is precisely what is needed to evoke the practical sympathy of the charitably disposed in support of this most beneficent work.

Another work of charity, smaller in compass but of special interest to medical men, which has been an object of no little solicitude to our readers and ourselves during the past year, is that carried on by the Council of the Royal Medical Benevolent College at Epsom. This most admirable undertaking has long suffered from want of funds and the combination under one roof of an asylum for the old and a seminary for the young—an arrangement which tends not only to overcrowd the available space, but also to hamper the due and efficient performance of the educational work. The excellent results which, in spite of this very serious disadvantage, the teachers engaged there have been able to secure have afforded proof enough that there is in them a capacity for doing good work and accomplishing great things in this department, which merits much more ample recognition than it has yet received, and we have never entered with a more cordial goodwill upon any task than upon

HOSPITAL DRESSER'S TABLE

THE utility of this table, which is made by Mr Alfred Carter of 47, Holborn Viaduct, E C, will be apparent on examination of the accompanying illustration. It has a

entire length of the table, so as to be available from either end. The bottom shelf is useful for bowls &c There is also a towel rail at the back The table is mounted on

solid marble top with lodges and rails, a sliding slab for cutting and preparing bandages &c There are two drawers divided into compartments These drawers run through the

strong brass castors and is strongly made in polished birch, forming a compact, useful article It will be a boon to some of our large surgical wards

"THE LANCET" SPECIAL COMMISSION ON MALARIAL FEVER IN TROPICAL AFRICA

THE following gentlemen have sent answers to our queries —

Anderson, D E, MD Paris MB, BA BSC Lond,
MRCS, LRCP, LSA Lond, Rue du Bois de
Boulogne, Paris

Battersby, C F Harford, BA MD, BC Cantab, MRCS,

Wilson, E M, MRCS, LRCP, Surgeon Captain, AMS,
Gillston road, South Kensington, London

agreement on the subject. Take, for instance, one point one-half of our correspondents, in reply to our query about rigors, say that they do not occur in malarial fever, the other half say that they form an invariable symptom of the disease. Again, most of the observers have apparently been unable to ascertain anything regarding the condition of the blood or of the urine in patients suffering from malaria, and for want of definite facts in regard to these two points we are, of course, unable to come to any conclusion about them or to collate them with LAYERAN'S and other researches. With respect to the so-called Blackwater fever in Africa, what are we to hold as a correct view? We have heard of Blackwater fever in America and in various other parts of the world, but when we come to investigate and analyse the reports of it in West Africa we are bound to confess our inability to form any definite opinion on the subject. The difficulty we experience, moreover, in estimating the value of conflicting opinions is that we have no detailed results of any examination of the blood or urine.

Thirty or forty years ago it used to be dogmatically held that some forms of yellow fever might be considered as only varieties of malarial fever. How can this, however, be reconciled with the investigations which have recently been made into the subject of yellow fever by FREIRE of Rio and others? We want our correspondents to try, so far as they are able, to contrast the differences between yellow fever and severe forms of malarial fever, and also to estimate the relations, if any, which exist between enteric fever and malarial fever. We cannot help thinking also that, notwithstanding the heat and discomfort of a residence in Africa, it is possible to make more careful and detailed investigations than have hitherto been undertaken as to the condition of the urine and other excreta of patients suffering from these diseases.

THE more we think of the new departure in diploma granting contemplated—for it is as yet, we believe, only contemplated—by the University of Edinburgh the more are we convinced that it needs to be very much criticised. If there is one thing of which authorities on medical education are convinced it is that examinations are becoming a great evil. No doubt to a certain extent they are a necessary evil, but nevertheless they are in themselves a very serious evil. To propose five brand new examinations is an astonishing proposal. For it must be understood that these are not to supersede any existing examinations. The unfortunate graduate who has been under the delusion that in taking the degrees of a great University he was doing something extra—something above what was required by the mere licensing bodies—is to learn that his degrees are “lower degrees” that have been obtained by mere “elementary training”—that the real distinctions are now to begin by acquiring from one to five diplomas, which are to put his degrees into the shade, each to occupy at least one special year of study and to be the subject of a special examination.

No matter how a student may distinguish himself in his classes during the ordinary curriculum and in the examinations for the existing degrees, honours are not to accrue to him as they have hitherto done. “Honours” are to be reserved for those taking the ulterior courses and examinations required for the fantastic process of specialisation, who are also to be rewarded with a diploma guaranteeing them to

be precocious rhinologists, cardiologists, nephrologists, gynecologists and hallucologists!

These proposals are a long step towards the fulfilment of that prophecy of Dr HERON WATSON that ere long the process of medical education and qualification will bring the student up to the ripe age of forty years. There may be worldly wisdom in such proposals from the University standpoint, but from the standpoint of the student—of his health and his fitness for the practical work of his profession—we very much question the wisdom of prolonging his stay in Edinburgh, where the clinical field—of prime importance in respect of special medical work—is notoriously inadequate for even the existing number of its students.

So far as we are able to divine the motives for this new departure, they will be found in a belief that it will add to the attractions of Edinburgh as a medical school and enable it the better to compete with London as a school of practical and clinical teaching. Edinburgh is a great school, a great centre of medical education, and nothing but grievous errors of judgment and taste on the part of her leading teachers are likely to alter that fact. But surely she is in some danger of falling into such errors at the present moment and in this new movement, for what does the very statement of it involve? First, it involves a disparagement of her degrees—they are to be eclipsed by her diplomas—a reversal of all academic conceptions of the respective value of degrees and diplomas. Her graduates cannot but resent such distinctions, and her detractors will be ready to point the finger of disparagement at her degrees and will be able to quote in justification the language of her own professors. The prestige of the University of Edinburgh is enough to sustain her for centuries yet to come in the first rank of medical schools if she will but recognise the limitations of her field, especially of her clinical field, and sustain above all things the high character of her proper medical degrees. Surely the more unprejudiced of those interested in the welfare of the Edinburgh school must see that by promoting this scheme of special diplomas Edinburgh is only likely to demonstrate her weakest point. They must see that if specialisation in diplomas is to be accepted it will not stop at Edinburgh, or at the other Scottish Universities to which the new medical ordinance of the Commissioners applies equally as to Edinburgh. London and Manchester will be able to assert a still stronger claim to be schools of specialism. So long as Edinburgh holds high the standard of her graduation and can honestly show that it is higher than the standard of the corporations she is on strong and dignified ground. When she attempts to take the initiative in creating a race of pretentious specialists that can have had but little practical experience she immediately descends to vulgar ground on which she can easily be beaten. We have nothing but pleasure in seeing schools competing to give to their pupils the greatest amount of special and valuable teaching in practical subjects, and we are well aware that Edinburgh contains a number of able and accomplished teachers, intra mural and extra mural, far beyond her mere professorate, who are eager to find a proper recognition and emolument in connexion with the large number of students that still flock to her school. Such men ought to find ample function and recognition with the

that of assisting in the movement which has been set on foot for improving the accommodation and making a more suitable provision for the pensioners than can be afforded at Epsom. We have not so far secured all the support for which we have hoped from our professional brethren, and it has been found impossible to realise the conditions upon which we as Proprietors of THE LANCET promised a subscription of £1000 towards the fund. In these circumstances the gift has been unconditionally made, and although it would have given much greater satisfaction to be able to announce that the generosity of the public had floated the scheme we are sanguine that that satisfaction is only delayed. Still, it must not be forgotten that in these matters time is all important. Every year that slips by while the conditions of work at the school remain unimproved means so much time actually lost to useful work. In this, as in so many other instances, it is eminently true that *his dat, qui cito dat*.

We trust we may not be considered egotistical if we point out that from the date of its foundation, on October 5th, 1823 to our present issue of Jan 7th, 1893, THE LANCET has been uninterruptedly under the actual editorial direction of members of the family of its founder, THOMAS WAKLEY, M.P. He, after many years' active work as Editor, was succeeded by his son, JAMES G. WAKLEY, M.D., since whose death in 1886 THE LANCET has been conducted by the present Editors, THOMAS WAKLEY, F.R.C.S. Eng., and THOMAS WAKLEY, jun., L.R.C.P. Lond., son and grandson respectively of its founder, who devote themselves exclusively to this work and do not permit themselves to become concerned in any professional engagements or business relations that might possibly render them less able to deal disinterestedly with the various matters which from time to time come before them in their capacity as Editors of THE LANCET.

The year upon which we have now entered will bring its own tasks and its own enlargements of the tasks with which in previous years we have grown familiar. We are sanguine of being able to meet them as they arrive chiefly because we are confident that never before has the support of the medical profession been extended more ungrudgingly to us and the interests to which our efforts are devoted than at the present time. It needs no great discernment to foresee that in this year 1893 knowledge will be increased and the interchange of views and opinions will be promoted in an even more than usual degree. It is not impossible that grave anxieties may lie in wait for us, for a recrudescence of the cholera epidemic of 1892 could hardly have less than very serious consequences in 1893, and he would indeed be a sanguine man who would count with any confidence upon a total escape of the civilised world from such a mishap. But be that as it may, we have at least this firm ground of satisfaction in looking forward into the uncertain and impenetrable future. We know that it will be our privilege to represent a profession which will acquit itself worthily. An unbroken past justifies us in saying that, whether the lot of the medical practitioner be cast in times of public quiet and prosperity or in times of disease and stress and storm, he will be found exhibiting qualities worthy of his calling and his post. At leisure he will be found diligently prosecuting those researches which lie at the foundation of his arts—in the place of

danger and in the hour of distress he will be found administering needed help with self forgetful devotion to a nobly conceived duty, and in either case he will humbly but not unworthily fill the office to which he has been called—an office than which none is more fitted to awaken and satisfy a generous ambition among all the varieties of human duty.

In our issue of July 2nd, 1892, we published a leading article referring to a commission which we had appointed to elucidate the occurrence and phenomena of malarial fever in Africa. At the same time we issued a schedule of questions which we hoped would be widely answered, as we sent them to many hundreds of practitioners who had been or who were practising in various parts of Africa. Accompanying the schedule, in most cases, a special letter was sent, calling attention to our endeavours to clear up as far as possible the difficult points which still surround this subject and asking our correspondents to do their best to aid us in an inquiry which we believed would be of the greatest use, not only to our colleagues who are bearing the burden and heat of the day in distant lands, but also to their patients and indeed to mankind in general. When so much has been done to investigate and elucidate the etiology of phthisis and cholera, it certainly seems remarkable that the medical officers of our army and navy, as well as the useful and too often ignored colonial officials, should not be able to do more than they have done in the past to clear up the etiology of a disease which above all others has been the bane of tropical life.

Notwithstanding all the letters and communications which we have received upon the subject during the past few years the response to our present inquiries has not come up to our anticipations. Up to the present date only twenty-four gentlemen have been kind enough to meet our desires by answering the detailed queries which we addressed to so large a number. It is quite possible that the distance of so many of our colleagues from the ordinary postal communication explains this fact, but of one thing we are sure—that the answers we have received have more than justified our wish to investigate the subject of malaria in Africa. They have already shown that up to the present time the various observers have been very far from agreeing in their estimate as to the essential nature of malaria. Some, indeed, of our correspondents seem to think that malarial disease does not even exist, others that what is termed "malaria" is only another name for chill, and others, that the disease in question is only a peculiar derangement of the so-called heat-regulating centre.

We do not wish in any way to forestall the outcome of our inquiry, which will prove, we are sure, of considerable interest. We would, however, again ask as many of our correspondents as possible to answer the questions which we have addressed to them. They have been able, no doubt, to form some opinion on the matter and, as we have taken considerable trouble to specify the various points upon which there appears to be most diversity of opinion, we hope that many will make a special effort to send us their observations in regard to them.

A glance at the reports which have been received shows how important it is for widespread information to be gathered before there can be any hope of ultimate

and pure and honourable he bore on his shield a device by which, even with visor down, he could be recognised by the spectators. The choice of such an emblem with its companion motto was one of great importance and came to distinguish its bearer not only in tournament but in stricken field. "The old order," indeed, "change'h," but this especial custom clings to the knight errantry of the modern day—the knight errantry that in the arena of journalism does battle for freedom and reform, for the suppression of the impure and the vindication of the salutary and the good. Instances of a happy choice of emblem or rubric by the leaders of the public press will at once rise to the mind, and we may be excused if, after the attainment of our "threescore years and ten," we revert for a moment to the name of THE LANCET. It was the chosen appellation and device of a medical journal started to combat jobbery, with its "bloated armaments" (to borrow Lord BEACONSFIELD'S phrase), the professional "close boroughs" and all their attendant rapacity, corruption and inefficiency. Plethoric corporations, which had battered on the unrecognised and unrequited work of generations of sound and self-denying public servants demanded a treatment with alteratives the efficacy of which had to be ensured by local and periodical depletion. That the therapeutics in question were sagaciously conceived and effectively carried out is now matter of history, which has put on undying record the name of its practitioner as well as that of the instrument with which he practised. The physician or surgeon of the present day, brought up under the free and openly competitive system for which THE LANCET lived and laboured, requires some effort of imagination to realise the "close-time" of seventy years since—metaphorically speaking, he must "see these roads before they were made," to appreciate the tunnelling, the blasting, the levelling up and the levelling down, begun and completed to construct the highway over which he is now wafted in his sleep. Nor was it in the British Isles alone that the work of THE LANCET was conspicuous. Imitation—that sincerest form of flattery—followed its lead in continental Europe and even in the new world, and to combat a similar state of professional torpor and corruption many journals, borrowing the name and the style, if not the skill, of the parent, arose throughout Christendom. Our correspondents at the central European schools might usefully make a survey of the history of their medical journalism and show how many a capable and well inspired organ adopted the title and the methods and achieved something like the reforms of its London progenitor. Let one instance suffice. Fifty years ago Holland took a mighty lead in physiological and pathological research chiefly under the auspices of the great GERARD JOHN MUTTER and his disciples. To further the reforms it had promoted in doctrine and in teaching his school started a special organ and the name assumed for it was the *Nederlandscher Lancet*. Under DONDERS (the great ophthalmologist) and his hardy less able co-peers, ELLERMAN and JANSSEN, the journal rose to fill something like the place occupied by its London namesake, inasmuch that in 1837 at the memorable first meeting of VIRCHOW and MOLESCHOTT, the young German pathologist told the young Dutch physician that the *Nederlandscher Lancet* aroused his admiration and enthu-

siasm. To this Netherlands copy of a British original the surgery and medicine of Teutonic Europe owed a revival—so true it is that the initiation of nobly inspired reforms is not only a good in itself, but a cause of good in others. Indeed, THE LANCET'S true monument is "Circumspice"—an all round comparison of "the professional status and standards of to-day as contrasted with those of "seventy years since", and it is a monument in which (whatever the inevitable streaks in the marble) its founder would have taken pride for its realisation of all he held most dear.

Annotations.

"Ne quid niteris."

PREPARING FOR THE INTERNATIONAL MEDICAL CONGRESS

ONE of the great medical events of the year now opening will be the International Congress of Medicine and Surgery to be held in Rome on Sept. 24th 30th. Committees, Italian and foreign, have worked effectively with the central Comitato Organizzatore for the elaboration of its programme and for the convenience and comfort of its participants, but it is in Rome itself that, naturally and properly, the greatest activity still prevails. Not only is the Policlinico in whose magnificent halls the sittings will take place still far from completion, but the other hospitals throughout the city require ameliorations neither few nor small to fit them for the scrutiny of the medical world from such centres of civilisation as London, New York, Paris, Vienna and Berlin. Of this no one is more sensible than the President of the Congress, Dr. Baccelli, himself. One of the very busiest men in Christendom, he has assumed an extra burden of thought and care in view of the 'march past' of Italian medicine before the critical eyes of Europe and America, and no effort is being spared on his part to make every arm of that "service" appear as capable and effective as possible. Meanwhile the physicians and surgeons of other nationalities who intend to assist on the occasion have also their special duties to perform. One of these is that of fitting themselves as far as they find it practicable for the part they have to play not only as audience but even as protagonists. More than one British consultant and academic teacher—a yet larger number, we believe, from Germany—are prepared to read papers and contribute to the discussions in the language of Italy, and we cordially congratulate them on their having so qualified themselves. The accomplishment, we are quite sure, will be found to be much more common among our representatives than is generally admitted—a "working knowledge" of Italian, by which is meant ability to read or even write it, being far more widely diffused among the profession than its censors think. This knowledge has only to be carried a step farther—has only to call in the aid of the 'parlato' to become available for conversation or spoken discussion. To such as have still that "working knowledge" to acquire there are various avenues to it possible. One is the time-honoured recourse to grammar and dictionary followed by the perusal of a standard author—a method by no means unpleasant when pursued with such a beautifully scientific manual as Dr. Demattio's 'Grammatica Italiana,' Innsbruck, 1875, combined with such an excellent 'Vocabolario' as Fanfani's (Florence, 1891) and applied, let us say to a comedy of Goldoni. Another and much more expeditious way is that recommended by our own Milton and Locke—to wit, comparing a good English translation of an Italian work with the

existing numbers, which, however, are said to show some falling off in consequence of the greater care and attention given in England of late years to practical teaching. By all means let the Scottish schools develop their practical side to its utmost and curtail their systematic lectures, and let her younger teachers who devote themselves to practical and clinical classes share in the dignity and the profit of University work. What we object to is the multiplication of examinations and diplomas with the admitted purpose of multiplying specialities instead of raising the standard of the existing degrees. Edinburgh will be judged by her graduates and not by her specialists, and her best friends will sincerely rejoice to hear that she hesitates to set the example to other examining bodies of a most doubtful new departure.

We have said nothing as to the registrability of such diplomas. The ordinance may receive the sanction of the Privy Council, which we believe to be necessary for all such ordinances. But we do not understand that they will have any claim to be registered under the Medical Acts in the sense in which sanitary diplomas were made registrable by the Act of 1858. The promoters of this most doubtful scheme have not yet submitted it to the judgment of the Medical Council. If we appear to speak severely on this subject it is from no want of interest in the University of Edinburgh—a University which has numbered amongst its graduates the names of WATSON, of WALSH, of MURCHISON, of STOKES and CORRIGAN and GRAVES, as of ALISON and SYME and CHRISTISON—but for the very opposite reason—our desire to see the leading University of Scotland maintain her high and her deserved reputation.

We commented in a recent issue on a request which had been made by the chairman of the Cornwall County Council to be supplied by the various local medical officers of health, on special forms compiled by the county council, with a number of data relating to vital statistics and general sanitary administration, and we expressed the opinion that if the county council desired information of this sort they ought, in the first instance, to appoint a county health officer. We now find that somewhat similar requests are being made by other county councils, who, whilst they do not hesitate to make demands for information which can be neither properly compiled nor properly utilised without medical judgment, send out notices as to their requirements without any offer of a fee for services rendered and without having any official means of putting the information in question to its proper uses. At Paignton in Devonshire the information has been distinctly refused by the local board, and the time has come when some general action should be decided upon, in view of the attitude adopted by some county councils.

Under the Local Government Act and the Orders of the Local Government Board the local medical officer of health is required to give to the county council or county councils of the county or counties within which his district is situated the same information as he gives to the Local Government Board with regard to any outbreak of infectious disease and to transmit to them copies of his annual report and of all special reports. We need hardly remind our readers that at the Local Government Board all such information and reports are submitted to the judgment of a

skilled medical staff, and since the Local Government Act provided for the appointment by county councils of a medical adviser it may naturally be assumed that it was the intention of the Legislature that these bodies should act in this respect in the same way as the central authority. But the reverse is the case, and a number of county councils, forgetting that it has been held necessary that the public health affairs of each constituent district should be carried out under the guidance of a local medical officer of health, fancy themselves competent without any such corresponding officer to deal comprehensively with the health and sanitary administration of whole counties, and, further, finding themselves in some difficulty because they have no medical adviser, they, in the first place, seek to obtain a great deal of information in excess of that which even the central authority deem necessary, and they then proceed to ask the local health officers to give them for this purpose their gratuitous services. Had they asked the clerks to the various sanitary authorities to compile the desired returns on the same terms the scheme would speedily have collapsed, but medical men have, in dealing with individual cases of health been so liberal in giving gratuitous advice and services that even authorities having all the public rates from which to draw do not hesitate to ask for similar gratuitous help when public questions are involved.

The Devon County Council have even discussed the question of reporting the Paignton Local Board to Whitehall as a 'defaulter,' but the proposal was wisely dropped. Other county councils have made certain representations as to default to the central authority, but we believe we are right in stating that the Local Government Board have never sent one of their own inspectors to investigate the question of default, except in regard to counties for which a medical officer of health had been appointed—that is to say, in cases in which the complaint of the council as to local default in protecting the public health was presumably based on proper medical judgment.

For the present it seems to us that local health officers are entitled to remember that their services belong only by right to the bodies by which they are appointed, and that, except where they desire to assist a colleague who holds the post of county health officer, they should supply to county councils no other information than that required under statute or official order, except on payment for their services, and even then only after having obtained the sanction of their authorities. Some local authorities have felt that the attempt to secure information through their health officer has amounted to an attempt to place that officer in the position of a complainant against the body whom he professedly serves, and they have warned him accordingly. One other point deserves to be borne in mind. Medical members of county councils will, we feel sure, not give such services to their councils as will go to uphold those bodies in their attitude of refusing to appoint a county health officer, and the existence of a medical practitioner, whether retired or not, on a county council should not be regarded as a reason for supplying any such council with information beyond that which it is the duty of a health officer to submit to the county authority.

WHEN a star of chivalry—a GODFREY or a DUGUESCLIN—rode into the lists to fight for his ideal of all that was fair

expressing our thanks to the Presidents of the Royal College of Physicians of London, the Royal College of Surgeons of England and the General Medical Council respectively for their courtesy and kindness in devoting considerable time and trouble to the administration of the Fund. Forms of Application to the Almoners of the Fund will be printed in our next issue.

THE PREVALENCE OF SMALL-POX

SMALL-POX still continues to spread, but with the exception of Manchester, where there are now seventy cases, the attacks in any one town or district are not numerous. The number of attacks in certain given places during the past week was ten at Chadderton, six at Wakefield, six at Liverpool, eight at Southampton, five at Halifax, four at Barnsley, and three at Sheffield. Amongst other places attacked are Batley, Bradford, Brighouse, Derby, Dewsbury, Doncaster, Durham, Newcastle, Huddersfield, Keighley, Leicester, Rotherham, South Normanton, Norwich, Runcorn, Sunderland, West Hartlepool and Warley. In several instances, as for example in Norwich, Newcastle, Doncaster and Durham, the disease has found access to the workhouses, and in a number of instances where hospital provision has long been delayed hurried arrangements are being made for some improvised schemes. At the end of the year there were thirty one small-pox patients under isolation by the Metropolitan Asylums Board. Small pox has now been steadily maintained since last September, and not only does the number of places attacked tend to increase, but the number of persons notified to be suffering from the disease is also on the increase. Notification returns are only available for a limited number of towns, but where they are available they show that a larger number of people were last week suffering from small pox than at any time during the present prevalence except in one single week—viz., when the Warrington epidemic was at its highest.

THE NATIONAL SOCIETY FOR THE EMPLOYMENT OF EPILEPTICS

UNDER this title a Society is being formed which will have for its object the provision of occupation for epileptics who are capable of work, but debarred from finding employment by reason of their affliction. A movement in this direction was commenced a few years ago in connexion with the Charity Organisation Society, when Miss Nina Paget read a paper on the subject, but the matter was not then actively pursued. Early last year, however, the subject was again taken up (with the active sympathy of the Charity Organisation Society) by the late Lady Taunton and by Miss Bardon-Sanderson, sister of the well-known professor of physiology at Oxford. The urgent need of provision being made in this direction had long forced itself upon the attention of these ladies, as a result of their experience in visiting the wards of the National Hospital in Queen Square. They were continually meeting with cases showing the cruel hardship inflicted upon numbers of willing and capable men and women by the nature of the disease under which they were labouring. The committee now engaged in taking the initiatory steps in the formation of a Society which certainly deserves, and we have no doubt will obtain, very widespread support, includes the names of Lieutenant-Colonel Montefiore, Dr Buzzard, Dr Ferner, Dr Howard Tooth, Prebendary Harry Jones, Messrs Pearman and Micholls, and several ladies. An office has been established at 20 Hanover Square, where Dr Low, Secretary of the Society *pro tem* attends daily from 3 to 4 o'clock. Miss Bardon-Sanderson is honorary secretary, her address is Branksome, Fitzjohn's Avenue, N.W. The Lord Mayor has kindly granted permission for a public meeting in support of the National Society for the Employment of Epileptics to be held at the

Mansion House on Wednesday, Jan. 25th. On this occasion it is expected that the objects of the Society will be explained and advocated by the Lord Chancellor, Sir Andrew Clark, Sir Walter Foster, M.P., Mr Haldane, Q.C., Sir James Crichton Browne and others. The subject is exciting great interest and a full attendance at the Mansion House may be looked for. The Society proposes to start in England (not many miles from London) a colony of epileptics who will find congenial occupation adapted to their varying capacities. The advantages of the colony will be obtainable by payment, the rate of which will be generally very moderate, but it is intended in process of time to make provision also for members of a higher class, whose contributions would be a valuable help towards the very large expense necessarily attendant upon the working of a colony of this description.

NEW YEARS HONOURS

WHILE we gladly congratulate Sir Anthony Colling Brownless, the Chancellor of the University of Melbourne, on his promotion, we are compelled to express our regret that there is no indication in the honours list of the national gratitude for the successfully combated invasion of the dire plague which has decimated many towns of Asia and Russia, and notably a great seaport of Europe, and which effected a footing, but, happily, no more than a footing, in our own country. We confess that some more conspicuous evidence of Royal, that is National, recognition of the profession whose duty and honour it is to face the dangers of combat with the King of Terrors, whatever his method of attack, would have been hailed by us with pleasure. Were we cynically inclined we could recall that wisdom of our folklore which notes the sanctifying influence of adversity and the tendency for saintliness to disappear on the disappearance of danger.

THE BREAK-DOWN OF THE "UMBRIA"

THE mishap which overtook the *Umbria* in mid-Atlantic and occasioned widespread alarm both here and in America, though now happily passed, has emphasised the serious peril which is involved in trusting to the capabilities of a single propeller however excellently constructed and skilfully worked. A break-down must occasionally happen whatever measures may have been taken to prevent it and then if no provision has been made for efficiently navigating the disabled ship an emergency arises which is most painful to contemplate. In some of the best ships afloat the propeller consists of twin screws, and if one should become incapacitated the other can still be relied upon with no worse result than some small delay. We believe that we are correct in stating that upon one of the voyages which the *City of New York* made last year one of her screws became disabled, but the ship, instead of becoming unmanageable, was propelled by the uninjured screw alone at a rate of seven teen knots an hour. If this be correct, surely no sea-going steamer should be built without this most necessary equipment of duplicated propelling machinery.

ABUSE OF HOSPITALS ABROAD

THAT this is not the only country where hospitals intended for the poor are made use of by the well-to-do is shown by a report which has been laid before the Paris Municipal Council by the Seine Medical Association, which collected various facts relating to the abuse of the Paris hospitals. On interviewing the officials of the Assistance Publique the representative of the *Temps* was assured that precautions are taken which necessarily render such abuses exceedingly rare. It was explained that though every patient whose case is grave is admitted to the hospital, inquiries are made by the administrative agents. If any are found not to be in

original on the opposite page. It is astonishing how soon a little perseverance in this practice enables the reader to break through the crust of a foreign tongue and acquire idiom and vocabulary enough to dispense with the translation and make his way through the original text. After this, to perfect his knowledge with a grammar is an affair of "leaps and bounds." There need be no difficulty in selecting a book in Italian, rich as the language is in translations of standard English medical works, to which the reader will come already more than half prepared. The Neapolitan school has signalled itself by its wealth of English medical literature transferred to Italian, any volume of which, begun by the British student on the method we have indicated, might form an easy and effective introduction to the language. Here too the much maligned "Latin fetish" intervenes as a positive "*Deus ex machina*" and proves to its erstwhile unwilling votary a blessing in disguise. That the course we have recommended is practicable even for the busy teacher or consultant Lord Dufferin has shown in his memorable discourse to the St Andrews' students in April, 1891. That, abroad at least, it is constantly pursued is seen in the autobiographical allusions of such men as Donders and Moleschott in medicine and Prince Bismarck in diplomacy. Once acquired, the language need not be dropped, but may be used in intercourse, scientific and social, ay, even in consultation with the foreign physician at one or other of the many Mediterranean or Alpine health resorts. Even for its own sake, as Mr Gladstone reminded us the other day, Italian is a precious acquisition. "I will contend with you from morn till dewy eve," said the right honourable gentleman to the late Sir William Gregory, who was urging the superior claims of German, "that Italian does more for the mind." To this contention our own profession can supply auxiliaries, even from the medical commentators and interpreters of Dante himself. But, not to digress further and to return to our theme, there can be no doubt that those who assist at the next great parliament of the healing art will have special reason to congratulate themselves on whatever acquaintance they may have cultivated with the *genua loci* and its language.

OUR HOMELESS AND NOMADIC POOR

THERE are three groups of the above—the first typified by the vagrant, the second by the huckster, the third by the gipsy. The vagrant is absolutely homeless, leading an "any port-in-a storm" life, and as the day closes "making a bee line" for the casual ward. The huckster practises as a Jack of all trades, but posing as a specialist in the most lucrative one goes about in the van which is his home. The gipsy is the nomad, "pure" if not "simple," living in tents or bivouacking in sheltered nooks or under the brushwood of commons or moors. Numerical division of these groups is not easy, but the extent to which their mode of life creates varieties of disease or favours diffusion of the same admits of a readier answer. The vagrant whose native imbecility or inveterate indolence makes of life one "long strike" is seldom the prey to acute disease. He is short-lived and becomes prematurely old, but, in spite of the precarious conditions he "enjoys," he is generally exempt from epidemic or zymotic affections and particularly free from phthisical and such like ailments. But does he spread contagion? At first sight he seems specially qualified for this rôle. He travels up and down the country, he is uncleanly in his habits, he often wears the cast-off raiment of infected people, he not seldom herds together with others under a common roof. With all this he is not a disseminator of disease—not certainly in the sense in which school children are. The huckster in all the above respects exhibits a marked contrast to the vagrant. Epidemic ailments are frequently his portion. His children are often

scrofulous, feeble and radically unhealthy, the adults especially being victims to "the most fatal of all English diseases—consumption." Dr B W Richardson (to whose masterly memoir on the subject we owe much information), when physician to the Royal Infirmary for Diseases of the Chest, treated in the course of a few years nine phthisical patients all from one travelling van. Other thoracic diseases—asthma, bronchitis, cardiac affections—prevail among the huckster group, a prevalence which the same shrewd observer associates with their generally intemperate habits. The gipsies, finally, are "constitutionally a very healthy race"—more exempt from the fatal diseases that thin the community than any other class. This exemption, says Dr Richardson, whose knowledge of them and their ways is perhaps unique, is coincident with their retaining "their original nomadic mode of life." Once let them mix and live with the people generally and they suffer like their neighbours. Their most common enemy in the outdoor life they lead is rheumatism. Of an epidemic of variola among gipsies Dr Richardson has never heard, nor has he seen one of them pitted with small pox. In 1851 there was a severe outbreak of scarlet fever at Barnes, near which place he was practising, and at the same time and place there was a populous gipsy camp, but among their numerous children there was not a single case. One element in their favour seems to be their temperance, which also explains the considerable longevity which they reach. Their lives and characteristics, from a hygienic point of view, confirm the induction that "as soon as men begin to aggregate in close localities without due and proper sanitation and with too great a command of 'creature comforts' they contrast indifferently with their seemingly less favoured brethren who are content to confront nature in her wildest moods."

THE LANCET RELIEF FUND

THE fourth annual report of the Almoners of this Fund, which appears in another part of our present impression, affords, we venture to think, most gratifying evidence of timely help extended to recipients for whom it would be impossible not to feel in any case the very warmest sympathy. The interesting selections of extracts which they publish, from letters received by them, will give some idea of the various and pressing nature of the necessities to which they have ministered. The considerable number of the applications received on behalf of persons to whom no assistance could under the rules of the Fund be given is proof that the objects which it is intended to serve are still imperfectly understood. These objects are restated fully and clearly in the report, but it may be as well to mention here that, shortly and without any attempt at precision, it may be said that the cases with which the Almoners can deal are those, and those only, in which a pressing and temporary need has arisen which can be effectively met by the grant, as gift or loan, of a small sum of money, it being of course understood that the benefit is restricted to registrable medical practitioners and persons legitimately dependent upon such. No rigid limit has been placed upon the amount of the grant, but the present financial statement exhibits what is, we believe, the largest sum ever yet allotted to a single case, the amount being £50 granted by way of loan. It is another distinguishing feature of the present report that the sum provided for the service of the Fund during the year has been slightly exceeded, the expenditure being £304, whereas the income is £300. It is, however, very satisfactory to find that the means in this way provided for dealing with a particular class of calamity have been so closely approximated to the necessity provided against, as this statement shows. We desire to take the present opportunity of

servation from as pure a source as possible must not there fore be overlooked. According to recent reports it is liable to be entirely disregarded. One correspondent indeed speaks of ice being procured from a spot which forms the customary grave of dead cats, dogs &c. for the district. It is to be hoped that sanitary authorities wherever they have reason to suspect the occurrence of such a breach of wholesome rule, and indeed of ordinary common sense, will act with energy and repress the dangerous practice.

THE CHARITABLE BEQUESTS OF 1892

THE *Charity Record*, reviewing the charitable history of 1892, finds that the year has been distinguished by some very liberal bequests for the benefit of the sick, the poor and the aged. We cannot afford space to enumerate these, but the mention of the fact may stimulate others to make 1893 yet more distinguished. Rich men need not wait till they are dead to enrich the poor and to provide the sick with comfortable beds. It will immensely add to their own pleasure while they live to see the actual advantages of their liberality.

INFECTION BY MILK-SUPPLY

AMONG other possible sources of morbid contamination the dairy must not be forgotten, though we have happily ample reason to congratulate ourselves upon the comparative infrequency with which it has been found guilty of acting as a means of propagating disease. We cannot, however, blink the fact that it has thus acted. Establishments of this class, like any other, are of course liable to suffer from errors of drainage and impure water supply. Mention has recently been made also of the transference of disease by the milk-can, and it has been suggested that here we have to deal with an imaginary cause of mischief. We would not wantonly question the care ordinarily exercised by dairy men in cleaning their cans, but we are nevertheless unable to deny the possibility of contamination in the manner suggested.

SMALL-POX IN GLASGOW

THE last two cases which occurred in Glasgow were imported ones and were admitted to Belvidere Hospital on Dec 24th and 26th respectively. One was a navy, who appears to have contracted the disease in Edinburgh and was taken ill in a hut on the West Highland Railway tract at Ardher, by Loch Lomond, in Dumbartonshire. Most of the inmates of the hut accepted revaccination, two had already had small pox and all are being kept under observation with the exception of two who had gone on tramp after exposure to risk of infection and who are being searched for by the police. The other case admitted into Belvidere Hospital is believed to have been infected in Manchester.

DANGEROUS DRIVING

NOT even a cabman, however busy, will dispute the justice of the rule which obliges him to slacken speed at street crossings and points at which lines of traffic meet within a limited area. There is an obvious necessity for such regulation. "Furious driving" anywhere is subject to the same wise restriction. Unfortunately, however, such a term as this is a comparative one, and, as the sequel shows, it is liable to serious misinterpretation. Only the other day a hansom driver was thus briskly traversing Old Broad street, when in a careless moment the lash of his brandished whip flicked the eye of a pedestrian. The suffering thus occasioned may be imagined. Perhaps there is no form of injury which is, for its size, of more critical purport than an abrasion of the conjunctiva. Treated at once, it will probably do well, neglected or but half treated, as more commonly happens, its issue as regards the eye itself may be of the

most ruinous character. The fact that the injury has been inflicted by a dirty whip-lash will not tend to brighten the prospect of recovery. With such details of practice, however, we are not immediately concerned. Prevention is in this case both needful and feasible, and it is to be hoped that local civic authorities will use every possible means to remove the cause of this danger by moderating within due limits the driving pace allowed in all busy thoroughfares under their control.

TAKING THE OATH WITH UPLIFTED HAND

AT an inquest held on Dec 30th at Guy's Hospital Mr H. E. Durham, the house surgeon, objected to kiss the Bible in use on the score of possible infection and was sworn with uplifted hand. Mr Fredk. Charles Young, the house physician, who gave evidence in a second inquest, was sworn upon a new Bible. We may again remind medical witnesses that anyone who desires to swear with uplifted hand is not bound to give, nor is anybody at liberty to ask, his reasons for so doing.

THE PROJECTED NEW BOROUGH HOSPITAL FOR LEEDS

THAT intelligent "self help" which has done so much for the Anglo-Saxon in the past, whether at home or abroad, finds collective expression in the municipal life of the country. A common danger threatens a community, and like a fortified town of former times the drawbridge is lifted and the walls manned, the danger faced and means adopted for resisting the enemy, without a precipitate appeal to the central government, as in more bureaucratic States. Together with independence, however, the Leeds corporation has coupled intelligence in action. A sanitary committee duly appointed, and accompanied by Dr Cameron, the medical officer of health, has examined with care similar institutions at Hull, Newcastle, Glasgow, Nottingham and Bradford, before deciding upon the special form which their own hospital is to take. We learn that the committee meanwhile seems to favour a system of numerous pavilions which experience and scientific considerations alike undoubtedly indicate as the most suitable for the proper isolation and treatment of cases of infectious disease.

THE WEATHER AND PNEUMONIA

THE effects of various meteorological conditions upon the development of croupous pneumonia are discussed in considerable detail in Dr P. J. Kolski's graduation thesis in the University of Moscow. He gives statistics of the disease and of the different meteorological conditions in Moscow for many years past, together with elaborate coloured diagrams. He believes that though changes in the weather may not be the main cause of pneumonia, as they were at one time thought to be, still the modern tendency to ascribe everything to bacteria is to be resisted, for, according to his researches and observations, meteorological variations certainly play a not unimportant rôle in the etiology of the disease. Generally speaking it may be said that abnormal weather is favourable to the development of pneumonia. The greatest number of cases has been found to occur in Moscow under the following conditions: a temperature lower than usual with very few diurnal variations, abnormally high barometric pressure, a north wind of less than its ordinary force, and a small amount of rain or snow. Dr Kolski does not agree with Seibert that pneumonia is especially rife when there is an absence of parallelism between the temperature curve and the curve of relative humidity and he considers that the common opinion that strong winds are favourable to pneumonia has no foundation, for, as a matter of fact, the years when the wind has been high have been the very years during which there has been but little pneumonia.

necessitous circumstances and it is impossible to remove them, they are obliged to pay during the time of their residence in the hospital, if it is possible to remove them it is suggested to them that they should return home to be treated and leave room for those who are necessitous. The number of paying patients is limited. As regards out-patients, all applicants are admitted whose general appearance indicates that they are not well off, but they do not receive gratuitous medicine except in the special hospitals. In Belgium, according to *Le Scalpel*, it is quite a frequent occurrence for well to do people to come in their carriages from the country to the hospitals and to obtain not only advice but medicine gratuitously, thus injuring both the medical practitioners and the druggists.

THE RIGHT HON THOMAS HENRY HUXLEY

IN our notice of the honours conferred last year on members of the medical profession we inadvertently omitted the fact of the admission of Mr Huxley to the Privy Council. The Privy Council has not the same powers which it once had in English history, but it is still a body charged with certain important duties, administrative and judicial. The Medical Acts, the Dentists Act, the Pharmacy Act, the Destructive Insects Act, the Contagious Diseases (Animals) Act, the Veterinary Act—all involve the action in certain contingencies of the Privy Council. The Council has important duties in reference to the Universities and to elementary education. The addition of Mr Huxley to such a body is an obvious advantage, for which the public will be grateful to Lord Salisbury. It is besides a proper compliment to one who takes a deep interest in education from its most elementary to its most advanced forms and who in many respects is the most conspicuous and courageous scientific man of the country.

DIPHTHERIA AND BOARD SCHOOLS

THE interesting inquiry into the sanitary condition of the Yerbury Road School was resumed last Friday. The case for the defence was that, though the drains of the school were not absolutely perfect and were not free from some slight oozing when the water test was applied, yet that they were practically sound and sufficient. The pipes were laid in stiff clay and there was no possibility of any noxious gas escaping through any defective joint into the school. Dr Smith on two occasions made an investigation into the state of the school and on both came to the conclusion that it was unnecessary to close the school. He had been in close consultation with Dr Tidy, who pointed out that diphtheria was prevalent throughout a large area of the parish. The pipes were laid at a gradient of 1 in 400 feet for only a part of the distance—viz, 37 feet. He admitted in cross examination that some of the pipes leaked and that personally he would never have passed a drain that was laid in varying gradients. The interest of the case now rests in the visit of the magistrate to see the drains and in his judgment, which will be delivered on Friday, the 6th inst.

LECTURES AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE following are the lecture arrangements at the Royal College of Surgeons for the coming year. The first course of lectures will be given in the theatre of the College at 5 P M precisely. Professor O B Plowright will lecture on the Action of Fungi on the Human Body on Monday, Wednesday and Friday, Feb 6th, 8th and 10th. Professor H J Campbell will give three lectures on Monday, Wednesday and Friday, Feb 20th, 22nd and 24th, on Intestinal Parasites belonging to the class Nematoda. Professor B T Lowne will give three lectures on Monday, Feb 27th, and Wednesday and Friday, March 1st and 3rd, on the Physio-

logy of the Respiration, Circulation and Nervous System of some Invertebrata. Professor Charles Stewart will lecture on the Physiological Series of Comparative Anatomy in the Museum of the College on March 6th, 8th, 10th, 13th, 15th, 17th, 20th, 22nd and 24th. The second course of lectures, to be also delivered in the theatre of the College at 5 P M, on Mondays, Wednesdays and Fridays, is as follows. The Physiology of the Kidney, by Dr J Rose Bradford (Arris and Gale Lecturer), on May 29th and 31st and June 2nd. The Pathology of Tumours connected with the Bladder, by Mr J H Targett (Erasmus Wilson Lecturer), on June 5th, 7th and 9th. Injuries to the Epiphyses and their Results, by Professor J Hutchinson, jun, on June 12th, 14th and 16th. The Surgery of the Air Passages and Thorax in Children, by Professor Bernard Pitts, on June 19th, 21st and 23rd.

A MEDICAL CENTENARIAN

DR. SEVERIN WIELOBYOKI, formerly a Polish refugee and subsequently a naturalised British subject, who has been a resident in St John's Wood for some twenty seven years since his retirement from practice, will complete 100 years of life on Jan 8th. He has had a useful and romantic history and is to be entertained at a centenary reception by the President and Council of the Society for the Study of Inebriety on Jan. 10th, in the rooms of the Medical Society of London. Addresses will be presented from various public bodies and members of the Legislature and of the medical profession taking part in the proceedings.

A VICTIM TO SMALL-POX

NEWS reaches us to the effect that Mr William Summers M P for Huddersfield, has fallen a victim to malignant small pox at Allahabad, India. It is painful that men of promise, such as he was, should be thus cut off in the prime of life by one of the most preventable of all diseases affecting man, but it is even more painful when such a calamity is associated with an attitude such as he had taken, and which in itself doubtless stood in the way of his availing himself of a renewal of that protection against small pox which is afforded by a comparatively recent revaccination. We do not know precisely what views Mr Summers held on the subject of vaccination, but he was an avowed advocate of the anti vaccinationists in the House of Commons, and during the past session he put a number of questions to Mr Ritchie on behalf of that section. His last appeal was on May 12th, when he sought to press the question of legislation adverse to that which now exists as to vaccination. Even if, like some others who ask similar questions, he was not altogether an unbeliever in the power of vaccination to protect against small pox, his attitude was hardly one which could be regarded as consistent with resort to the only protection which could have availed to save life from this loathsome and formidable disease.

THE SOURCES OF OUR ICE SUPPLY

THE application of cold has by common consent been accepted as the best method of ensuring the preservation of dead animal or vegetable substances, and ice as the means best adapted to this purpose. In other words, extreme cold is incompatible with putrefactive or other bacterial action. This fact in some degree does away with the necessity for using in order to effect this purpose no ice but such as is itself free from any organic impurity. Only in a measure, however, for it has been repeatedly shown that bacteria, notwithstanding their inaction, can preserve their vitality at very low temperatures, while the alkaloid poisons developed by them are not in any way attenuated as to their virulence by any such variation in surrounding physical conditions. The return of a suitable temperature restores their opportunity, and a morbid process is bound to follow. The necessity of obtaining ice to be employed for meat pre-

THE LANCET

Special Analytical Commission

ON

MINERAL WATER MACHINERY AND METALLIC CONTAMINATION

It is well known that a solution of carbonic acid gas in water behaves as a feeble acid, and it has been assumed therefore that true carbonic acid H_2CO_3 is formed. This view is supported by experimental observation. The mass of carbonic acid, for example, dissolved by water at ordinary temperature and pressure increases as the pressure, but at a pressure of two, three or more atmospheres the mass of CO_2 dissolved is less than that calculated by the laws of Henry and Dalton. When the pressure, acting upon water which has been saturated with CO_2 gas is diminished, most of the CO_2 escapes, at first rapidly then slowly, the last traces of CO_2 can only be removed by placing the water *in vacuo* or by continued boiling. A striking piece of evidence in favour of this view that H_2CO_3 exists is afforded by the fact that the metal magnesium reacts with a solution of CO_2 in water as though a free acid were present, hydrogen being evolved and magnesium carbonate formed in accordance with the requirements of the following equation— $H_2CO_3, Aq + Mg = MgCO_3 + H_2$. Still further evidence towards this view is furnished by the fact that water holding in solution carbonate of sodium or potassium dissolves considerably more CO_2 than pure water, definite salts known as bicarbonates being produced, $NaHCO_3$ and $KHCO_3$. Blue litmus again, turns wine red in aqueous solution of CO_2 , the blue colour returning on exposure to air, but in contact with the moist gas at pressures only of one to two atmospheres it becomes vermilion red as though it had been exposed to a mineral acid. The affinity or combining power of CO_2 is, however, small, for the carbonates which in this respect simulate the sulphites (SO_2 derivatives), are readily decomposed by the common acids.

If water saturated with CO_2 gas under pressure contains true H_2CO_3 , then some explanation of its action upon many metals based upon this hypothesis might be expected. A short time since some experiments were instituted in THE LANCET laboratory to ascertain which metals and especially which of those used in the manufacture of beverages, are acted upon by carbonic acid. For this purpose pure specimens of lead, tin, copper, antimony and iron were selected. Clean bright pieces of the metals were placed in ordinary water, CO_2 was bubbled through for some time and the solution then decanted, filtered and examined. The following observations were made—Lead was dissolved in considerable quantity as carbonate, the metal showing unmistakable signs of corrosion, and on boiling the solution a precipitate consisting of basic carbonate subsided. Tin did not appear to undergo the slightest change and the liquid when tested gave only a faint and doubtful reaction. The water containing the copper strip gradually assumed a green colour and on boiling the filtered solution a considerable precipitate of green copper carbonate was obtained, just as on boiling the CO_2 out of hard water chalk ($CaCO_3$) is precipitated. Zinc was even more energetically attacked, it became covered with a loosely adherent white powder and the filtered solution gave strong reaction for zinc, while zinc carbonate was abundantly precipitated on boiling. Antimony was found to dissolve to a slight extent only, and this did not appear to be influenced by the CO_2 , as it was also found to dissolve in small quantity in water not charged with CO_2 . Iron was strongly attacked the solution on boiling giving a dirty reddish brown precipitate. No precautions were taken to exclude air from the water through which the CO_2 gas was bubbled.

It seems evident from these experiments that ordinary water containing an excess of carbonic acid gas is capable of taking into solution distinct quantities of lead, copper and zinc, but not tin—possibly carbonates are formed which dissolve in an excess of CO_2 . Although in the case of magnesium (vide *supra*) hydrogen is evolved, no hydrogen was evolved in the above experiments, the CO_2 would therefore seem to act as

a feeble acid upon a film of oxide of the metal formed by the action of the oxygen in the water, unless it is that hydrate is first formed (as might be the case, more particularly with lead), which is then rapidly converted into soluble carbonate by the excess of CO_2 . Precisely similar actions occur of course with the mineral acids. Thus, while hydrochloric acid does not dissolve copper, it readily dissolves the oxide or hydrate forming copper chloride. Acetic acid, again, rapidly dissolves oxide or hydrate of lead forming acetate, but the pure metal is unaffected.

In the laboratory during the ordinary course of analytical work we have invariably found traces of copper in soda water, but, although there are instances on record of lead having been found, we have never met with a single sample so contaminated. Copper, for various reasons, is in fact, largely employed in the construction of aerated water machinery. According to our experiments, however it would be better to employ tin, and then contamination of aerated water with injurious metals would be entirely avoided. But tin is not so workable as many other metals, it is too soft for some uses and too brittle for others, while it is very expensive. In spite of these drawbacks, however, we have recently inspected some soda water machines in which it is impossible for the water to come in contact with any other metal than the purest tin, and tin is for all practical purpose as good as the noble metals gold, platinum and silver. Even the joints in these machines are thickly lined with tin, and all leading pipes are made of block tin. We visited the premises of the well known engineers Messrs Hayward Tyler and Co., of 90 and 92 Whitecross-street, E.C., where these machines are being made. The condensers of these machines, in which the carbonated water is contained under pressure before being drawn off into bottle, are made of copper thickly lined inside by a special and ingenious process with the purest grain tin. Larger condensers are made of best gun metal, in which case they are silvered. The water is conveyed into and from this condenser also through tin piping, the joints of which are of the same metal. We secured samples of the metal so used, and also a specimen of syphon heads which was sent to THE LANCET laboratory and examined. About the purity of the metal used for the lining process there can be no doubt whatever, for the mean result of several analyses gave the quantity of chemically pure tin as 99.90 per cent. Water saturated with CO_2 was then placed in a copper cup similarly lined with tin and specially made for the purpose of these experiments, and left for several days. The metal showed no signs of deterioration, while the minutest test failed to indicate even the smallest quantity of metal in the liquid. The syphon head was found to consist also of tin, with a small proportion of antimony the antimony being used in order to make the heads durable, but it is important to add that neither lead nor copper was found in any single instance. It may be remarked that copper or other metal tinned in the ordinary manner is not satisfactory and once the copper is exposed the solvent action proceeds with comparative rapidity. But in the machinery made by Messrs Hayward Tyler and Co a definite thickness, one-eighth of an inch perhaps, is laid by a special process upon the metal, so that flaws due to excessive thinness of the coating are not possible, the "life" of the apparatus is thus almost indefinitely prolonged.

Soda water machinery has been brought during recent years to a marvellous pitch of perfection, and it is doubtful whether any other industry has made such rapid strides in so short a time. But the recent improvement which Messrs Hayward Tyler and Co have effected is one entitled to the greatest praise, inasmuch as its object is to secure a greater degree of purity in a beverage that is very generally consumed. It must be admitted that the introduction of plant that will turn out 150 dozen of soda water per hour, about which there cannot possibly be the slightest suspicion of metallic contamination, is a distinct advance and one calculated not only to confer benefit on the community, but also to add considerably to the interests of the mineral water industry.

PRECAUTIONS AGAINST CHOLERA.—In order to promote uniformity of action on the part of the various port authorities of England in view of the possible appearance of cholera this year a conference of delegates has been arranged by the Port of London Sanitary Committee. The meeting will be held at the Guildhall at an early date, under the presidency of the Lord Mayor.

MICRO-ORGANISMS OF ULCERATIVE ENDOCARDITIS

A PAPER on the above subject appears in the *Lyon Médicale* of Dec 18th, 1892. The case upon which the observations were made was that of a girl aged nineteen. The diagnosis was confirmed on post mortem examination. In order to procure the organisms one of her fingers was carefully cleansed, first with soap and water, then with ether and finally with corrosive sublimate solution, a drop of blood was obtained by pricking the finger with a sterilised needle and placed in bouillon. The culture medium was kept at a temperature of 35° C, and rapidly became cloudy. On microscopic examination a diplococcus was found rather larger than the staphylococcus pyogenes. The elements of the diplococcus appeared occasionally to be single, but they never formed in chains or in groups. They did not possess a capsule. The organism stained well with all the aniline dyes and also by the Gram method. It could be cultivated at any temperature between 13° and 14° C. The cultures in bouillon very quickly caused a turbidity in, and gave a well marked yellow tinge to, the liquid. The culture obtained its maximum of growth in about forty eight hours, but ceased to increase in about seven or eight hours after that time. A copious yellow deposit formed on standing, but the supernatant liquid remained cloudy. Cultures on agar agar glycerine grew rapidly, and well marked colonies were observed at the end of twenty four hours at a temperature of 37° C. On the surface of the cultivating medium a very slight white pellicle was noticed with somewhat festooned borders, this appearance extended into the agar agar. If a culture was made by running the needle deep into the agar agar, a white streak was produced in the course of the needle, but it presented nothing which could be called characteristic. On gelatine the diplococcus did not grow so well—the gelatine was not liquefied. Occasionally on the surface a pellicle similar to that produced on agar agar was noticed. In plate cultivations this was shown to consist of minute, opaque, yellowish white colonies. A rabbit was inoculated with a broth culture, but no effect was produced. The animal was killed on the tenth day, but no lesions could be detected.

FOREIGN UNIVERSITY INTELLIGENCE

Florence—Professor Celso Pellizzari of Pisa has been appointed to the chair of Dermatology and Syphilis in succession to Dr Pietro Pellizzari, deceased.

Leipsic—Dr Spalteholz, formerly assistant to the late Professor Braune, has been raised to the rank of Extraordinary Professor.

Lemberg—Dr L. Niemilowicz has been appointed Extraordinary Professor of Pharmacognosy.

Marburg—Dr Eugen Korschelt of Berlin has been appointed Professor of Zoology and Director of the Zoological Institute.

Pisa—Dr G. Guarnieri has been promoted to the Ordinary Professorship of General Pathology.

Santiago (Chile)—Don F. Paelma Tupper has been appointed Professor of Experimental Physiology, Don Aureliano Oyarzún, Professor of Morbid Anatomy, Don L. Espejo Varas, Professor of Therapeutics and Materia Medica, and Don Francisco Servat, Professor of Organic Chemistry.

Toulouse—M. André has been appointed Professor of Internal Pathology.

Turin—Dr Camillo Negro has been appointed *privat-docent* in Neurology.

DEATHS OF EMINENT FOREIGN MEDICAL MEN

THE deaths of the following distinguished members of the medical profession abroad have been announced—Dr Bonalumi, Professor of Military Hygiene in the Florence

Medical School—Dr Reeves Jackson, Professor of Gynaecology in the College of Physicians and Surgeons, Chicago.—Dr Jas R. Leaming, Professor of Pulmonary Diseases in the New York Polyclinic.

THE Royal Academy of Sciences of Turin have announced that the competition for the Bressa Prize, commenced on January, 1891, will extend to December, 1894. As is already known, the prize will be given to the scientific author or inventor, whatever may be his nationality, who during the interval included in the four years mentioned shall have made, in the judgment of the Academy, the most important and useful discovery or published the most valuable work on physical and experimental science, natural history, mathematics, chemistry, physiology and pathology, geology, history, or geography and statistics. The value of the prize is fixed at 10,416 francs. The works must be printed, and the productions of the unsuccessful candidates will be returned to them.

THE following gentlemen have during the last month been selected for enrolment as Honorary Associates of the Grand Priory of the Order of the Hospital of St. John of Jerusalem in England, by the Chapter of the Order, in recognition of valuable and gratuitous services in the cause of ambulance work, and their selection has received the approval of Her Majesty the Queen, the sovereign head and patron of the Order. Frederick Gordon Brown, M.R.C.S. (City of London), Samuel Osborn, F.R.C.S. (London), Geo. Edward Shuttleworth, M.D. (Lancaster), Thomas Coke Squance, M.D. (Sunderland), George Arthur Barr, M.R.C.S. (Newport, Isle of Wight), Professor John Chiene, M.D. (St. Andrews Ambulance Association, Edinburgh).

PROFESSOR NATHANAGEL of Vienna, the worthy successor of the illustrious Professor Bamberger in the chair of Clinical Medicine, has just intimated to the organising committee of the International Medical Congress that he will contribute a special paper to the agenda of one of the general sittings.

THE Lettsomian lectures will be delivered at the Medical Society of London, Cavendish square, by John Syer Bristowe, M.D., F.R.S., on Jan 9th and 23rd and Feb 6th, 1893, at 8.30 P.M., on the subject of Syphilitic Affections of the Nervous System.

THE General Medical Council has appointed Mr Rawdon Macnamara to be visitor of the examinations of the English Universities and the medical corporations in Ireland for the current year.

THE MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—On Friday next, Jan 13th, a general meeting of this Association will be held, at 3.30 P.M., in the rooms of the Medical Society, Chandos street, Cavendish square. The President, Dr W. Howship Dickinson, will occupy the chair, and a paper on the Disinfection and Treatment of Scarlet Fever by Antiseptic Inunction will be read by Mr J. Brendon Curgenven. The meeting will be open to all medical men who take an interest in the subject of the paper and they will be invited to join in the subsequent discussion.

LITERARY INTELLIGENCE.—A new medical monthly entitled *Annales Médico Chirurgicales* has just been commenced under the auspices of a Belgian Medical Society, Le Cercle Médical Borain. It is principally devoted to clinical observations made by the members—Havana (Cuba) has just produced a new monthly—*La Abeja Médica* (the Medical Bee). It is edited by Dr Gustavo López y García. The specimen number which has been sent to us contains, amongst other articles, an illustrated paper on Deformed Skulls of Carribean Indians in Cuba and St. Domingo, by Dr Sotolongo y Lynch.

absolutely no action, but that menthol, on the contrary, even in very small doses, arrested the abnormal action of the yeast. Finally, in another series of experiments made with the grains of rye Dr Herz found that the temperature of those vessels which were infected with putrid matter was higher than that of those which contained rye germinating in the ordinary way.

LOSOPHAN

Losophan may be looked upon as a tri iodide of cresol. It contains 80 per cent of iodine and is soluble in alcohol and readily taken up by fatty substances. Dr Snielfeld¹ finds a 1 per cent ointment exceedingly valuable in skin diseases due either to vegetable or animal parasites, as tinea tonsurans and pityriasis versicolor, for pediculi capitis and pubis, 25 per cent of vinegar is added to the ointment, and in the case of scabies a stronger preparation is employed containing 2 or 3 per cent of losophan. In chronic skin infiltrations an ointment of the strength of 1 or 2 per cent. was very useful, but in acute eczema it appeared to be irritating. In prurigo sycoide vulgaris, acne vulgaris and rosacea, and in pruritus it was very effectual. It appears to be of little use, however, in gonorrhea or urticaria and is contra indicated in acute inflammatory affections of the skin.

THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS

By F J MOUNT, LL.D., M.D. EDIN., F.R.C.S. ENG.

I

' Finis coronat opus.'

FOR more than a century past what is now known as the "hospital question" has excited interest and attention throughout Europe, and particularly in France and England. Works of high authority have been written on the subject based upon the personal and practical experience of distinguished members of the medical profession closely connected with the study and practice of the healing art in its application to the relief of sickness and injuries, and the advancement of the science of which it is the outcome. It has also attracted, particularly in our own country, the earnest sympathy and active support of those philanthropists who have laboured much amongst the poor, and know what misery and suffering are endured by them from causes mostly beyond their control, when struck down by accidents or diseases which imperil their lives, temporarily or permanently impair their usefulness, and in too many cases break up their homes, subjecting their families and themselves to the pains and penalties of destitution.

I hold it to be imperative upon all engaged in the consideration of questions of such magnitude and importance in their social and scientific relations to study carefully their history before attempting to suggest remedies for the removal of such defects in their working as diminish or destroy their usefulness, and to introduce such improvements as experience and the advance of science may suggest.

From our national and healthy proclivity and propensity to self reliance in all difficulties and dangers to assist ourselves and to deal by voluntary effort, whenever and wherever practicable, with such evils as are susceptible of mitigation or removal in our social system, the charitable aspect of medical relief has naturally become one of the leading factors in the assistance of those who are unable to assist themselves, when compelled to resort to public institutions for relief in sickness. I regard the collection of funds for the maintenance and proper working of hospitals as the first step of importance in the proceeding, and not the be all and end all of its disposal, which, in my humble opinion as a hospital physician and administrator in the early years of my official career is the successful treatment of disease, the provision of relief to the really poor immediately it is required, and the advancement of medicine in its curative preventive and educational aspects. If private charity is unable, in the exceptional vastness of the greatest number of human beings ever collected in a restricted space to provide the means of accomplishing all that is expected—nay, even demanded—from it in existing circumstances, is there no *via media* by which State aid and private benevolence may not join hands to complete the work without violating the sound economic principles on

which both are based? This is a question which I shall consider further on. My present object is to give a necessarily brief *résumé* of the history of hospital management in the present and past century by a notice of a few of the works which have exercised the greatest influence upon it.

The earliest authority of repute who has dealt with the whole question in a strictly scientific and practical manner, is M. Tenon in his "*Mémoire sur les Hôpitaux de Paris*." He was an eminent professor of pathology, who was selected to report upon the reconstruction of the Hotel Dieu after its destruction, and his work was published in 1788, a little over a century ago. After obtaining all the information he could procure on the hospitals of Italy and Germany, he came to England, was in personal communication with the leading medical authorities of the time and visited most of our best and greatest hospitals, which he evidently examined with scrupulous care. He was much struck with the hospital at Plymouth, built upon the pavilion principle and devoted to the treatment of 1200 inmates. His inquiry was devoted principally to the management and structural arrangements of all these institutions, and on his return to Paris he embodied the results of his observations in his celebrated work, in which every branch of the subject was specially treated. He regarded the Plymouth Hospital as

"le plus bel et plus parfait pour sa destination" which he had visited and throughout his treatise evidently refers to much of what he had seen, but guarded himself from expressing approval or disapproval, on the ground that in all cases hospitals must fulfil their special purposes, subordinated to conditions of climate, surroundings, manners and customs and all other details which must be in harmony with the national peculiarities of each country and people. His work was approved of by the Academy of Sciences and of Surgery, and pronounced in its construction and arrangements to have omitted or forgotten nothing while nothing in it was out of place. His work may still be studied with advantage, for in his own country it has continued to exercise considerable influence, and has not been without effect upon our own.

In this country, in 1796 an eminent surgeon and earnest philanthropist Sir William Blizard of the London Hospital made a partially successful attempt to point out for correction some of the most prominent technical and general defects in the then existing hospitals. His contention was contained in a few brief notes was restricted in its scope, and attempted no systematic view of the subject. Such as it was, his action was in advance of his time. In another paper, entitled "*Propositions for promoting the Usefulness and Prosperity of Hospitals and other Public Charities*" he advocated the formation of a "*mutual aid society*" to harmonise and connect the actions of the managers of hospitals and other charitable institutions by an annual stocktaking of their respective charges with a view to remedy imperfections and errors and introduce such changes and improvements as seemed to be desirable after personal examination and discussion.

This sound and sensible proposal was suited to the character of the time, but although correct in design, it failed in execution. Sir William Blizard considered that hospitals, being strictly public institutions whatever their endowments had public duties to perform and were thus directly responsible to the public for their acts. Hence he was of opinion that their removal from public control was injurious to them, as when societies intended for general benefit become wholly independent of public opinion there would often be "a disposition to abuse the means at their disposal, so that with private interests as a ruling principle of action the expectations of science and humanity are disappointed." He also indicated the fallacy of parading numbers as tests of success, and pointed out more than one practice which needed amendment then and some of which are still in existence and need it as much now.

The subjects of hospital reform and of Poor-law reform received vigorous treatment from the pen of Thomas Wakley the founder of THE LANCET, who from the foundation of that periodical, notwithstanding much interested opposition, did not hesitate to expose abuses both as regards the medical staff and the management. A reference to the Editor's notice in 1824 will show that so far as reforms of various sorts were concerned, "THE LANCET had not existed in vain. He did not restrict his asseverations to literature but boldly advocated in Parliament the thorough reform of these institutions.

From the beginning of the present century and for many years afterwards the subject attracted little public attention, and produced no such lasting record as the work of M. Tenon or

¹ Therapeutische Monatshefte No 10 1892.

Pharmacology and Therapeutics.

THE TREATMENT OF ACID DYSPEPSIA

M BAUDET, in a recent communication to the Société de Thérapeutique, stated that he found this condition was frequent amongst persons with a rheumatic diathesis. He regarded the following symptoms as characteristic: Inaction of the skin and liability to cold, tendency to over secretion of hydrochloric acid and to dilatation of the stomach, tendency to fermentative changes, liability to constipation and hemorrhoids, formation and absorption of toxins, from which headaches resulted, and the formation of gas within the stomach. The condition of the skin was to be relieved by warm affusions, by friction with a horse hair glove, by exercise and warm clothing. To counteract the over secretion of hydrochloric acid he thought it advisable to employ articles of diet which are rapidly removed from the stomach (eggs, milk, vegetables) and to forbid the consumption of meat and the use of wine and alcoholic drinks, while allowing the use of non effervescent alkaline waters. The tendency to fermentative changes and the absorption of toxins were to be counteracted by internal antiseptic treatment. He considered benzonaphthol preferable to naphthol, which is too caustic, and to rasprol, which is too soluble. Salol, though good as a disinfectant, possessed an odour which many patients could not tolerate. Salicylate of bismuth was also recommended in cases where the kidneys were free from disease. Benzonaphthol in most cases should be used in doses of five grammes twice a day with the principal meals. The dose of salicylate of bismuth given in the same way is from two to three grammes. It is well to give magnesia with salicylate of bismuth to counteract the constipation from which these patients habitually suffer. The action of the intestine might also be favoured by the use of gassia.

DULCINE

Under this name a new substance has been described which, on account of its sweet taste and its complete freedom from toxic properties, appears likely to attract attention. It is obtained by means of para phenol carbamide, a compound prepared in 1883 by Berthierblau at which time the manufacture was hampered by its great cost. A new process has, however, been discovered which will in all probability reduce the price sufficiently to allow of general use.

THE IDENTITY OF CAFFEINE AND THEINE

In consequence of various statements that the physiological action of theine obtained from tea differs in certain respects from that of caffeine obtained from coffee, Mr W R Dunstan and Mr W F J Shepherd have sought for evidence of isomerism in these bases and have published their results in the *Pharmaceutical Journal*. Having extracted theine and caffeine, they found that the two substances melted at the same temperature—viz., 234.5°. From each base a crystalline auro-chloride was prepared, and these two salts melted at the same temperature—248.5°. The complete correspondence in the properties and composition of the auro-chlorides afforded satisfactory evidence of the absence of a structural difference in the bases. The mercuric chloride compounds derived from each melted at the same temperature and exactly corresponded with each other in other respects. Considering the complete identity of caffeine and theine to have been thus demonstrated, Messrs Dunstan and Shepherd think the observed differences in their physiological action must be ascribed either to impurities in the specimens used or to variations in the animals employed in the experiments. In the course of their investigations two new auro derivatives of caffeine were obtained—an aurochlor caffeine and a caffeine potassium auro chloride.

INDIAN OPIUM

At a meeting of the Pharmaceutical Conference the opinion was expressed that there was no reason why India, instead of Turkey, should not supply the whole world with medicinal opium. Native opium is medicinal purposes in India, and the receipt of a medicinal opium issued by the Medical Store Department, Bengal has enabled Dr B H Paul and distinguished member to institute comparisons with a good sample. The Patna opium in the state have been announced 32 per

cent of moisture, in the dried opium the amount of morphine was found to be 8.55 per cent. A tincture made with the dried opium according to the directions of the Pharmacopœia yielded on evaporation to dryness a residue of extract amounting to 21.3 grams per fluid ounce. The amount of morphine contained in the tincture was 2.74 grams per fluid ounce. The sample of Turkey opium in the dry state contained 10.84 per cent. of morphine. The extract yielded by the tincture amounted to 19.8 grams per fluid ounce and the amount of morphine in it was 3.4 grams per fluid ounce.

TOXIC PROPERTIES OF OXIDE OF ZINC

Oxide of zinc is so commonly employed externally that the possibility of toxic action when used internally in large doses has been generally overlooked. It has been found by MM L d Amore, C Falcone and L Marmaldi that in dogs toxic symptoms resulted from the daily administration of fifty centigrammes of oxide of zinc, death occurring within from ten to fifteen days. The symptoms noted were repeated efforts to vomit, weakness of movements, partial loss of sensation, wasting, diminution in the quantity of water, which was high coloured and contained hæmoglobin, albumen and sugar, and a partial destruction of red corpuscles. After death the tissues and organs were found to be remarkably pale, while the liver, kidneys and pancreas presented evidence of fatty degeneration.

EUCALYPTOL

Eucalyptol is a crystallised bichloride of eucalyptene which has been prepared and examined therapeutically by Dr Lafage de Neully, and which, according to an article he publishes in a recent issue of *Les Nouveaux Remèdes*, presents great advantages over all other preparations of eucalyptus having a definite composition and a uniform action and being entirely innocuous. This body occurs as white scales having a special odour, almost tasteless at first, but after being a short time in the mouth giving a slightly bitter taste. It is soluble in ether, chloroform, fatty and volatile oils and alcohol, which last, however, partially decomposes it. It is almost insoluble in glycerine and in water, alkalies decompose it. It is highly antiseptic, infinitesimal quantities being sufficient to prevent putrefaction in liquids containing organic substances, but it does not interfere with the action of ferments such as diastase, pancreatine and pepsine. Experiments on animals showed that when administered by the mouth elimination takes place by the lungs and also by the bowel and urine, but when given hypodermically elimination takes place almost exclusively by the lungs. Its physiological properties appearing to indicate that it should have a therapeutical action on respiratory, digestive and perhaps also on kidney affections, about 150 clinical observations were conducted to test its value. In phthisis it was found useful in allaying the cough and other symptoms. The alkalinity of the intestine causes eucalyptol to break up thus deodorising the canal by means of greasy aromatic products of decomposition, and several cases of severe diarrhoea have been rapidly cured by it. In typhoid fever, too, it has been given with satisfactory effects. Observations on urinary diseases have not as yet been made. Eucalyptol is best administered in powders or in capsules, from fifteen to twenty two grains may be given per diem, this quantity being divided into several doses, which are best taken during the interval between meals. Children of four or five years of age may be given six to eight grains during the twenty four hours.

PTYRINIA IN UNICELLULAR ORGANISMS

Dr Max Herz of Vienna has made some experiments showing that unicellular organisms attacked by microbes suffer from fever in exactly the same way as more complex organisms. He made his observations on yeast cells. After determining the quantity of carbonic acid developed in a certain time during ordinary fermentation produced by the cells, he tried to infect them by adding to the fermenting liquid a few cubic centimetres of a putrid liquid. Infection appeared to take place, producing an increase of carbonic acid and a rise in the temperature of the liquid. If instead of the ordinary putrid liquid, this same liquid heated and filtered, was added, the change was much less marked. It seems, therefore, that it is possible to produce by microbic infection a true fever in unicellular organisms similar to that of human beings. Dr Herz then studied antithermic action on the infected yeast of certain chemical antipyretics. He found antipyrine had

absolutely no action, but that menthol, on the contrary, even in very small doses, arrested the abnormal action of the eos. Finally, in another series of experiments made with the germs of rye Dr Herz found that the temperature of those vessels which were infected with putrid matter was higher than that of those which contained rye germinating in the ordinary way

LOSOPHAN

Losophan may be looked upon as a triiodide of cresol. It contains 80 per cent of iodine and is soluble in alcohol and readily taken up by fatty substances. Dr Sanfeldt finds a 1 per cent ointment exceedingly valuable in skin diseases due either to vegetable or animal parasites, as *trinea tonsurans* and *trichiasis versicolor*, for *pediculi capitis* and *pudis*, 25 per cent of vinegar is added to the ointment, and in the case of calives a stronger preparation is employed containing 2 or 3 per cent of losophan. In chronic skin infiltrations an ointment of the strength of 1 or 2 per cent was very useful, but in acute eczema it appeared to be irritating. In *prurigo*, *psoriasis vulgaris*, *acne vulgaris* and *rosacea*, and in *pruritus* it was very effectual. It appears to be of little use, however, in *eczema* or *urticaria* and is contra indicated in acute inflammations of the skin.

THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS

By F J MOUNT, LL D, M D EDIN, F R C S E. G

I.

"Finis corona opus."

For more than a century past what is now known as the "hospital question" has excited interest and attention throughout Europe, and particularly in France and England. Works of high authority have been written on the subject, based upon the personal and practical experience of distinguished members of the medical profession closely connected with the study and practice of the healing art in its application to the relief of sickness and injuries, and the advancement of the science of which it is the outcome. It has also attracted, particularly in our own country, the earnest sympathy and active support of those philanthropists who have laboured much amongst the poor, and know what misery and suffering are endured by them from causes mostly beyond their control, when struck down by accidents or diseases which imperil their lives, temporarily or permanently impair their usefulness and in too many cases break up their homes, subjecting their families and themselves to the pains and penalties of destitution.

I hold it to be imperative upon all engaged in the consideration of questions of such magnitude and importance in their social and scientific relations to study carefully their history before attempting to suggest remedies for the removal of such defects in their working as diminish or destroy their usefulness, and to introduce such improvements as experience and the advance of science may suggest.

From our national and healthy proclivity and proneness to self reliance in all difficulties and dangers to assist ourselves and to deal by voluntary effort, whenever and wherever practicable, with such evils as are susceptible of mitigation or removal in our social system, the charitable aspect of medical relief has naturally become one of the leading factors in the assistance of those who are unable to assist themselves when compelled to resort to public institutions for relief in sickness. I regard the collection of funds for the maintenance and proper working of hospitals as the first step of importance in the proceeding, and not the be all and end all of its disposal, which, in my humble opinion as a hospital physician and administrator in the early years of my official career is the successful treatment of disease, the provision of relief to the really poor immediately it is required, and the advancement of medicine in its curative, preventive and educational aspects. If private charity is unable, in the exceptional vastness of the greatest number of human beings ever collected in a restricted space, to provide the means of accomplishing all that is expected—nay, even demanded—from it in existing circumstances, is there no *via media* by which State aid and private benevolence may not join hands, to complete the work, without violating the sound economic principles on

which both are based? This is a question which I shall consider further on. My present object is to give a necessarily brief *resumé* of the history of hospital management in the present and past century by a notice of a few of the works which have exercised the greatest influence upon it.

The earliest authority of repute who has dealt with the whole question in a strictly scientific and practical manner, is M. Tenon in his "*Mémoire sur les Hôpitaux de Paris*." He was an eminent professor of pathology, who was selected to report upon the reconstruction of the *Hôtel Dieu* after its destruction, and his work was published in 1788, a little over a century ago. After obtaining all the information he could procure on the hospitals of Italy and Germany, he came to England, was in personal communication with the leading medical authorities of the time and visited most of our best and greatest hospitals, which he evidently examined with scrupulous care. He was much struck with the hospital at Plymouth, built upon the pavilion principle and devoted to the treatment of 1200 inmates. His inquiry was devoted principally to the management and structural arrangements of all these institutions and on his return to Paris he embodied the results of his observations in his celebrated work, in which every branch of the subject was specially treated. He regarded the Plymouth Hospital as "*le plus bel et plus parfait pour sa destination*" which he had visited and throughout his treatise evidently refers to much of what he had seen, but guarded himself from expressing approval or disapproval, on the ground that in all cases hospitals must fulfil their special purposes, subordinated to conditions of climate, surroundings, manners and customs and all other details, which must be in harmony with the national peculiarities of each country and people. His work was approved of by the Academy of Sciences and of Surgery, and pronounced in its construction and arrangements to have omitted or forgotten nothing, while nothing in it was out of place. His work may still be studied with advantage, for in his own country it has continued to exercise considerable influence, and has not been without effect upon our own.

In this country in 1796 an eminent surgeon and earnest philanthropist Sir William Blizard of the London Hospital made a partially successful attempt to point out for correction some of the most prominent technical and general defects in the then existing hospitals. His contention was contained in a few brief notes was restricted in its scope, and attempted no systematic view of the subject. Such as it was, his action was in advance of his time. In another paper, entitled "*Propositions for promoting the Usefulness and Prosperity of Hospitals and other Public Charities*," he advocated the formation of a "*mutual aid society*" to harmonise and connect the actions of the managers of hospitals and other charitable institutions by an annual stocktaking of their respective charges with a view to remedy imperfections and errors and introduce such changes and improvements as seemed to be desirable after personal examination and discussion.

This sound and sensible proposal was suited to the character of the time, but although correct in design, it failed in execution. Sir William Blizard considered that hospitals, being strictly public institutions, whatever their endowments had public duties to perform and were thus directly responsible to the public for their acts. Hence he was of opinion that their removal from public control was injurious to them, as when societies intended for general benefit become wholly independent of public opinion there would often be "a disposition to abuse the means at their disposal, so that with private interests as a ruling principle of action the expectations of science and humanity are disappointed." He also indicated the fallacy of parading numbers as tests of success and pointed out more than one practice which needed amendment then, and some of which are still in existence and need it as much now.

The subjects of hospital reform and of Poor law reform received vigorous treatment from the pen of Thomas Wakley, the founder of THE LANCET, who from the foundation of that periodical, notwithstanding much interested opposition, did not hesitate to expose abuses both as regards the medical staff and the management. A reference to the Editor's notice in 1824 will show that, so far as reforms of various sorts were concerned, THE LANCET had not existed in vain. He did not restrict his asseverations to literature but boldly advocated in Parliament the thorough reform of these institutions.

From the beginning of the present century and for many years afterwards, the subject attracted little public attention, and produced no such lasting record as the work of M. Tenon or

the brief notes of Blizard, who was, I believe, the originator of the Samaritan fund. The report of the great Poor law Act of 1834 does not appear to have directed any special attention to sickness as a cause of destitution, or to the provision of any separate institution for the reception of sick paupers. It drew, however, a distinction between indigence and poverty, which has not, I think, been as carefully observed since as it should be. The great awakening on the question of hospitals as charitable institutions occurred after the Crimean War and was, I believe, in a great measure due to the work and example of Miss Nightingale, to whom will always belong the transcendent merit of having taken a leading part in the introduction of some of the greatest, most enduring, and most valuable improvements in our hospital system. The discussion of the many aspects of the question has since been constant in our medical journals, in the proceedings of the Social Science Association and other kindred associations, as well as in special conferences of men thoroughly conversant with the subject, all of which failed to move the Government of the country to take any action in the matter until very recently. The persevering and ultimately successful and admirable procedure of the Charity Organisation Society deserves to be recorded most prominently. The action of the medical department of the Privy Council, prior to its absorption in the Local Government Board and the provision by the latter body of some of the best hospitals we have, are also very important incidents in the recent history of the question. In France, about the same time, when a third rebuilding of the *Hôtel Dieu* became necessary, the subject was again carefully investigated. To notice a title of the records of permanent interest accumulated in France and England at the time referred to would be impracticable, but in both countries exceptionally important results of the active labours of the period exist which deserve special mention. The first I will refer to is Husson's great "*Étude sur les Hôpitaux*," a magnificent contribution in every sense, which included, very much in the form adopted by M. Tenon, all particulars relating to the construction, arrangements, hygiene and professional works of hospitals in general, and of the proposed leading hospital of Paris in particular. It was published in 1862, was well illustrated and embodied the experience of its author when he was administrative head of the *Assistance Publique* in Paris. His department had previously sent a deputation of its chief medical and engineering inspectors to England to study our plans and procedure—Messieurs Blondin and Ser—who, after a minute and careful investigation, embodied the results in a special report which was also published *in extenso*. Between the French works and English reports are to be found all the particulars of two entirely different methods of dealing with the question, one altogether by State management and control, the other—our own—known as the voluntary system, which is chiefly under irresponsible private bodies, except in our Poor law hospitals and infirmaries which are under local public management, supervised by a special board of control, the Local Government Board, and thus become State institutions, so that we have both systems in our own hands, as guides in dealing with the question. A careful study of them, both by personal visitation and published records, has satisfied me that there are points of excellence in either which might be useful to the other, but that neither system in its entirety would be suitable for both for the reasons mentioned by M. Tenon and quoted above. To attempt to analyse the works referred to in detail would occupy more time than I can give to it, and more space than could be afforded me in the columns of *THE LANCET*.

Moreover, it is not necessary, until an analysis of the evidence produced before the House of Lords Committee and their report upon it have been scrutinised, to ascertain the remedial measures suggested to remove existing defects, regarding which so much diversity of opinion at present exists. The most scientific, reliable and important contribution to the question of the management of the civil hospitals of Great Britain is the report of Messrs. Bristow and Holmes on the inquiry conducted by them under the direction of Sir John Simon, whose attention was attracted to the subject by the absence of all trustworthy information regarding the sanitary circumstances of and medical and surgical work done in our hospitals. This invaluable record is contained in the sixth volume of the Transactions of the medical department of the Privy Council. It is divided into two parts. One part is devoted to the regulations of hospitals regarding the admission of patients, the kinds of diseases admitted or excluded, the separation or admixture of different classes of disease, to

the classes of patients admitted and to other minor particulars. The other division of the work is devoted to the construction of hospitals and both were reviewed by the head of the department, in a section of his introductory examination under the title of the "*Statistics and Hygiene of Hospitals*." The reporters visited Paris with a view to compare the French and English systems, as had been done in France, for our plans and procedure. The French hospitals were and are all Government institutions, although some of them were possessed of endowments insufficient for their maintenance, which were safeguarded by the State, but no private rights or interests in them were allowed, nor were they given any share in the management of the institutions to which they belonged. The State demanded that the hospitals should secure aid to all the sick poor of their respective departments, who would otherwise become a charge upon the public or be left to perish. A bed had to be found for every person poor enough and sick enough to require to be treated in a public institution. Their sick poor are thus more thoroughly succoured than are ours, without any intervention of a poor law. They regard some portions of our voluntary system of relief of the sickness of the poor as inhuman and unfit for introduction in France, where sickness and poverty alone are passports of admission.

The English report is very valuable on another ground, as showing in an exact manner the actual state of each of the many institutions visited and examined at that time. It may be useful to compare them with the evidence on the same points contained in the statements submitted to the House of Lords' Committee.

In 1881 I wrote a series of papers on the construction and management of hospitals, which were published in *THE LANCET* of that year. They attracted considerable attention at the time, and were in consequence in 1883 extended and embodied in a joint work by Mr. Saxon Snell and myself on the subject, all matters concerning construction by the former, the medical and charitable relations by myself. A second edition was called for and published in 1889. Both are now out of print. In the work referred to most of the matters which it was deemed desirable to refer to a Royal Commission are treated at some length, and in my inaugural address to the Royal Statistical Society, of which I was the President in 1890, a reference was made to the hospital question which I venture to reproduce now, as embodying a brief *résumé* of my views on the question.

"A Hospital Board for London."

"With the exception of the Poor law institutions, the hospitals of London are under no other control or supervision than those of their own establishments and supporters. They represent an order of things which in every other class of public institutions of like character has passed away. As a body or even individually they render no connected account of their proceedings in finance, medical statistics and similar matters of general and scientific interest, to enable the public or the profession to form a correct estimate of the worth of their work. All medical establishments of the character of hospitals are public institutions and essentially charities in their chief aim and purpose—the treatment of the sick poor—and should not be subordinated to any other use. From their very nature they need the most careful regulation and to be dealt with as all other charities are. No one has ever questioned the value of the work performed within the walls of those of established character. They are in this respect monuments of science, skill and philanthropy of the purest and most elevated type. But the isolated and independent action of the different institutions robs them of much of their usefulness and tends to impair the higher ends expected from them. We live in a time when combined action and organisation are the watchwords of the age and it is no reproach to the older institutions that in this respect they are not altogether in harmony with them. Their removal from strict public scrutiny is, in my belief, one of the reasons of the withholding of the pecuniary support which they formerly received, added to the phenomenal growth of the population of London which has outstripped the ordinary means of dealing with such difficulties. The remedy for the present evils, so forcibly represented in the memorandum of the Charity Organisation Society, will, I think, be found in the creation of a central board of supervision in which all the interests concerned should be fairly represented which should for the present, leave untouched the

usual procedure of all authorities connected with existing institutions, should have power of control and supervision similar to those now possessed and exercised by such a body as the Metropolitan Asylums Board, and armed with authority to call for detailed returns upon a uniform plan of finance and statistics, with a view to their digest and publication annually in such manner as may be deemed most useful. To enable such a body to be created so as to exercise effective control over the hospitals of the metropolis hospital London should, I think, be divided into five sections corresponding to the five registration districts, of which the population, as ascertained in 1881, is noted below:—

Districts.	Area in acres.	Population in 1881.	Number of persons per acre.	Number of hospitals in each district.	Number of hospitals to the square mile.	Number of beds.	Ratio of beds to the population—1 to
West District	10,820	699,023	64	5	17	4,497	149
North "	13,468	815,947	67	23	14	4,889	211
Central "	2,121	582,528	132	17	5.2	1,979	1.2
East "	5,510	692,732	126	15	17	5,717	121
South "	40,885	1,235,927	29	23	0.3	7,515	168
Total	73,804	3,916,430	51	111	0.9	24,097	159

The central board should contain representatives from all the great hospitals of the five districts should be distinctly elective in character, should consist of the lay and medical elements in equal proportions, and should comprise a sufficient number of members to admit of the formation of an executive committee for each district. It should perform in addition such of the functions of the Bureau d'Assistance Publique in Paris as can fairly be engrafted upon our manner of managing matters with no further assistance from the State than the bestowal of legislative sanction to so much of the plan as requires Parliamentary authority. To attempt in an opening address to work out this or any other scheme that may be suggested for so exceptional a city as London, is manifestly impossible, I must therefore content myself with its mere mention. In any case it will need much prolonged and careful inquiry to determine what ought ultimately to be done, and what is immediately practicable. Having referred to the Metropolitan Asylums Board as an institution of similar character I deem it right to bring to your notice its manner of performance of a most important part of its work—that which has immediate relation to the functions of this Society—the collection of statistics to illustrate the nature and results of its labours. The special duties of this board are to superintend the fever hospitals and pauper lunatic asylums of the metropolis, in the interests of public health and the prevention of the extension of infectious diseases. To this have been added the regulation of the ambulance system and the management of a trainship. The effective control of the spread of infectious fevers is a far more difficult task than the management of ordinary diseases and accidents inasmuch as the one only affects the individual, while the other, if unchecked, may become disastrous to whole communities. [The excellent manner in which its duties have been performed may be gathered from its published reports—models of their kind, such as no others of our public institutions afford.] If equally skilled care and attention are bestowed in the more extended control of the hospital system of London by a properly organised and authoritative central board the various faults found with the existing uncontrolled system can be dealt with in the only manner likely to be attended with success. The absence of a proper system of independent inspection and audit, the irregularities of the out-patients' departments, the regulation of the relations of the schools to the hospitals, the discipline, duty and training of nurses, the suppression of all useless or mischievous special hospitals and the prevention of the creation of others of similar character, the adoption, audit and publication of a uniform system of accounts, a scientific but simple collection and annual publication of the medical statistics of all hospitals on a uniform plan, the extension of institutions for the reception of convalescents and the various side issues which are constantly arising are all many-sided questions which require patient investigation by a skilled agency armed with authority to deal with them decisively before any change is attempted. All this is a question of time, for the radical

reform of old institutions to be permanent as well as to find acceptance, must be of slow growth. Structures, which from time to time need removal or renewal, should be built up again as much as possible on pre-existing foundations."

I have purposely restricted my remarks to matters which have come under the purview of the Lords' Committee, and I have not yet attempted the elaboration of a complete scheme of arrangements for London which will, if possible, bring public and private charity into harmony so far as can be accomplished without detriment to either. When the detailed statistics of the recent census of London as a whole are published I hope to be able to see my way to making the

attempt, but I regard the provision of a central board, if properly organised, to be the keystone of the arch, if armed with the requisite authority to accomplish the difficult task which will be assigned to it. Thus much of any plan of reform need not be delayed by any other consideration, and, it is hoped, may lead in the near future to the creation of a special public health department, under a responsible Cabinet Minister.

CHOLERA.

CURRENT NOTES, COMMENTS AND CRITICISM.

THE late recrudescence of the epidemic at Hambourg in the shape of a sharp outbreak disturbed the confidence of the officials and people of Germany and called attention to the fact that the danger is by no means past. The cholera record for Hambourg for Dec. 23rd showed seven fresh cases, one of which terminated fatally—four occurred in the city and three in the suburbs, that for the 30th included six deaths, one of which was in the shipping quarter and there were two fresh cases of suspected cholera. At the same date five deaths were reported in Altona and two in Wandsbeck, besides one case of suspected cholera. On the last day of the year there was one case notified at Hambourg and one on the first day of the present year and three cholera deaths were reported at Altona on the first-named date. As regards France, the bulletin from Paris for the week ending Dec. 29th showed two deaths as having occurred during the previous week. At Dunkirk three deaths occurred during the last week of 1892. The disease was also said to be spreading at that time at Grand Fort Philippe, near Gravelines, where sixteen deaths were reported on Dec. 25th and 29th. Several cases of "cholerae" were also reported in the neighbourhood of Brest and some suspicious deaths were said to have occurred among the navvies employed in the construction of a railway.

According to the latest reports from Warsaw cholera was prevalent in the government's of Radom, Lublin and Plock and huts had been erected on the Prussian frontier for the detention of travellers.

The weather on the continent of Europe appears to be very severe at the present time as it is in this country, and although the persistence of cholera in cold weather in districts and places where it has been previously prevalent is not by any means unknown, still it is extremely rare for the disease to extend itself or prevail with an epidemic force during the winter season. It is curious how the results of experience in France are corroborative of those of our own in 1865 and 1866, when cholera never attained any wide spread in the well-sewered towns of England and of that in Munich in 1873, when the properly sewered part of the town had only

half the mortality and sickness of those portions that were badly or not at all drained. What is wanted at the present time is a thoroughly exhaustive inquiry into the local spread of cholera, in places where all the circumstances are known and the various factors can be ascertained and determined.

CHOLERA IN FRANCE

(FROM OUR SPECIAL CORRESPONDENT)

DOMESTIC DRAINAGE

Necessary Measures and Measures immediately Applicable — The Pavé System at Harre — The Window Sinks and Slop Water Contamination. — Cholera Dens at Harre, Honfleur and Rouen — Befouling the Subsoil of Dwellings

It is universally acknowledged that "good sanitation" is the best protection against cholera, but it is important to add that in the term "good sanitation" must be comprised the condition of the subsoil as well as that of the houses standing on the soil.

The probable explanation of such difference will be attributable to the condition of the subsoil. But, it may be urged, how can the condition of the subsoil be altered? Above all, can this possibly be done before next spring, when cholera may return with increased virulence? Certainly want of time, but above all want of money, will render it impossible to carry out extensive works of sanitation between this and next spring. Nevertheless a great deal could be done. An entire system of sewers cannot be extemporised in a few months, nor can water be brought to a town in a similar period, but, if the streets must remain in an unsatisfactory state, there is no reason why the condition of each individual house should not be vastly improved. This may not altogether suffice to ward off the danger, but it will lessen the damage likely to ensue. In Normandy especially there are one or two measures which obviously should at once be applied. This is a matter which interests not only the inhabitants of Normandy, but also the British public. It must be borne in mind that a very large proportion of the fruit, the poultry, the butter and the eggs consumed in England comes from Normandy. That these provisions should reach us from a cholera stricken country is

FIG 1

No 17, Rue des Gallons at Harre The back yard.

If we only judge by what appears on the surface we shall often be surprised to find that quarters which seem most unwholesome are exempt, and other districts, less crowded, less dirty and poor, contribute the larger number of victims to the epidemic.

a matter which cannot be contemplated otherwise than with concern. Fruit and other provisions coming from Hamburg last summer were stopped in some of our Northern ports and sent back to Germany, if the much larger supplies shipped

to England from the ports of Normandy—Honfleur, Havre, Dieppe—were treated in a similar manner, the consequences both in England and France would be most disastrous.

Though it is not possible to build before next spring sewers and aqueducts enough to give a proper water supply and to efficiently drain all the towns that are menaced by the cholera epidemic, there is no reason why great improvements should not be effected in the domestic drainage of the towns in question. Throughout Normandy the subsoil of inhabited houses is saturated with slop water. The accompanying illustrations show how this occurs. For instance, No 17 Rue des Galons is one of the cholera stricken houses of Havre. This and the other houses at Havre were photographed by M. L. David, architect of the town. With him I visited the houses in question. The Mayor of Havre, acceding to my request that they should be photographed, was good enough to present me with copies, and the accompanying sketches are faithful reproductions of these photographs. The Rue des

the street door open this shut off the corner and ensured a certain privacy. When the street door was shut there was nothing to check the smells from the tub ascending into the building. In the wall near the tub a little hole had been made so that any liquid filth on the floor might flow out into the passage leading from the back of the premises to the street. Immediately opposite, on the other side of the passage, two more tubs were placed facing each other, under a staircase. There was not room to stand up under the steps and the corner was absolutely dark. A rough wooden seat was fitted over the tubs, but they were not closed, and gave forth horrible odours, which passed up into the house through the chinks in the stairs that covered them. The passage in which these pail closets were situated led from the street to an inner yard surrounded by dwellings four storeys high. In this roughly paved yard there were several costermongers' carts, and two more pail closets, standing side by side, near the entrance to the houses at the back of the yard and just

FIG 2.

No 21, Quai Colbert at Havre. The back yard.

Galons is one of the narrow streets in the Quartier Notre Dame, running down to the Grand Quai of the Avant Port, or tidal basin. (See map in THE LANCET of Nov 12th, 1892.) Entering a pail closet I found a badly kept ungal. A door on the opposite side served a double purpose. It was at once a closet door and a window. The closet consisted of a large tub placed in a corner. In the corner, there was no seat. By pulling

under a bedroom window. This will be noted in the accompanying sketch, and it will also be observed that the inhabitants of the room in question, not content with the effluvia from these pail closets keep a stock of parrots and other animals. The staircase being in the corner of the yard serves for the buildings on both sides of the angle. In this corner there is, on each floor, a large inner room, and on

the first floor this inner room, being surrounded by other houses, has no window, no light whatever. Yet this room, into which daylight has never penetrated, has been selected to serve as a common lodging house dormitory. There are seven beds in the room, let out at the very high charge of fifty centimes per night to promiscuous lodgers. On the second floor the corresponding room, in consequence of irregularity in the shape of the surrounding buildings, has a window, but it measures only one foot square. On the third floor the room has several small windows. Surely it would be possible to prevent persons sleeping in rooms that have no windows and where daylight can never enter. It will be seen also that there is room to construct more closets in the yard, so that the

happens that human dejecta are emptied into the sinks. The sink and the pipe beyond are greasy, filth adheres to the sides, and they give forth unceasingly the worst odours. Yet these foul smelling mouths are just at the windows of dwelling rooms, when the window is opened the inhabitants breathe air tainted by these sinks. Then the pipes and the sinks corrode, get out of shape, leak and render the walls damp and foul. But this is not the worst feature of the case. The slop water on reaching the bottom of the pipe does not go to a drain and to a sewer, it splashes into the yard, it slowly gravitates along a little gutter till it reaches the street gutter and thence goes to the nearest sewer. The process is well

FIG 3

The Impasse des Corderies in the Perrey District of Havre.

abominations under the stairs in the passage from the yard to the street might be abolished, but, apart from the abomination of these badly placed and badly kept pail closets, the disposal of slop water constitutes an organic defect which exists throughout Normandy, and this is well shown by the photograph. A receptacle called a *plomb* will be noted by the side of several windows, it is a sort of sink. Into this are thrown all the slops, here are cleansed the chamber utensils, and here are often left the dirty brushes and cloths &c used for such purposes. There is no flush or method of cleaning these sinks, and needless to say that, as the closets below are some distance away and are extremely filthy, it often

illustrated in the sketch of the house, No 21, Quai Colbert. In this case the engraving, which is from a photograph taken in the back yard, represents the back of the house that gives on to the street. The passage going under and through the house to the street is here seen, as are the slops from the dwelling within the yard flowing towards the street, but it will be noted that some stones and rubbish have fallen into the little gutter. This will check the flow of the slops and make them spread over the entire surface of the passage. The gutter itself is only a row of bricks laid flat against another row of bricks standing vertically so as to form a ledge. There is no cement used, between each brick the water can easily

pass into the soil below, while the surrounding pavement is so loose that the stones move under the weight of the foot and often splash up from underneath black, fetid mud. At the back of this narrow little court there is a small house, in the front of which there is a sort of wooden shanty. Its floor is 40 centimetres below the level of the yard and the place measures 2.37 by 2 metres. In this place a man, a woman and five children lived for a whole year. They were miserably poor people and their domicile was so utterly unfit for human habitation that no one had the audacity to levy any rent for such premises. These people were discovered by the police when the latter came to remove a cholera patient from the house. They had remained there rent free for a whole year, but the authorities took them all off to the sanatorium. These people, who were living in the confined space of about 60 cubic feet per person, threw all their slops out on to the yard of No 21, Quai Colbert. Even the tenant of the house in front found the space so confined that he built himself a sort of closet made of old planks, which is seen near the small first-floor window. Here was placed a wooden tub which served as a closet and which was emptied "when full"—that is, at no regular times. There is no water on these premises and of course no drainage beyond the surface drainage shown in the picture. The pipe down the wall fills buckets with rain water from the roof when it rains, and if other water is wanted the inhabitants must go down the street and get it at the public fountain. Rents for single rooms in such houses vary from 7s to 12s per month.

Even smaller are the houses in the Impasse des Corderies, where some of the rare cases of cholera which occurred in the Perrey district of Havre took place. This is a small street through which there is no thoroughfare and which consists almost exclusively of wooden huts. Some of these huts have but one room and one floor, the ground floor, and several are inhabited by washerwomen. This accounts for the number of large tubs outside the huts. The rooms are very low and the door in some cases only four to five feet high, so that it is necessary to stoop to enter. In one of these little wooden houses I found an old woman busily engaged in washing, not her own linen, but that of other persons. Across the dark, low room linen was hung up to dry. The wooden walls were black with cakes of greasy, adhesive dirt. In a sort of closet cupboard, partitioned off from the room by badly fitting planks, were lumber, coal, rags &c. and a wooden tub. This tub served as the closet of the house and its faecal contents spread foul odours throughout the hut. There were slops on all sides—on the black, dirty floor of the dwelling stagnating on the bare earth outside the door, or slowly travelling along the central gutter of the alley which constitutes the main and only drain of the place. On the opposite side the *tinettes* or pails were placed under the staircases leading to the little upper rooms in the roofs. Most of the inhabitants of this wretched quarter were dressed in mere rags. There were a great many poles to hang up linen or fishing nets to dry, and yet there is no provision made to drain away the dirty water from the washing tubs and the domestic slop-pails.

This custom of draining into the gutter cannot be abolished in a day. People must drain somewhere, and if there are no sewers and no cesspools, then the slop water must go to the street gutter. But the extraordinary feature of the case is that there seems to be no power of enforcing the construction of a proper drain between each house and the gutter. The municipal authorities may wash the street gutters, may render them water tight with cement &c., but they cannot call upon the householders to build drains so that the water going to the gutter shall not sink into the subsoil of the house. For instance, I went with the town architect, M. David, to No 28 Rue des Galions. There had been five cases of cholera in this one house. The police had gone there over and over again to clean the place out. Even the fire brigade had been brought on to the premises and they had so well washed out the stairs with the hose that a part of the rotting old structure had given way. A portion of the stairs had fallen in and the top floor could no longer be reached. Nevertheless, in spite of all this cleaning, we found the gutter that went through the passage from the back yard to the street blocked up and the slops instead of flowing to the street were stagnant under the house. In the Rue d'Albanie, which is but the continuation of the Rue des Galions, at No 66, we visited the inner yard. It is half roofed over and measures only six feet by four feet, and in this confined space there were ten gaping sinks outside the windows. From one of the pipes of these sinks we saw faecal matter oozing out. The house

was six storeys high and the pail closet was at the very top of the stairs. The pail stood on loose-fitting planks, urine and other filth dripping through the chinks on to the stairs underneath. Next door, at No 68, where there had been two cases of cholera, the pail closet was in the middle of the stairs and caused such foul odours that the tenants complained they could not keep either milk or soup, as it so soon turned sour. I was not surprised to hear at the Bureau d'Hygiène that the death rate in this street (Rue d'Albanie) calculated on the average of the last ten years, amounts to 41.1 per 1000, but in the Rue du Petit Croissant the death rate is 44.9 per 1000, and, as I have

FIG 4

The Rue des Rosiers at Rouen.

already stated on a previous occasion, it reaches the enormous proportion of 57.2 per 1000 in the Rue Marbonne, while in the broad, prosperous Rue François Premier it is only 12.03 per 1000.

At Rouen, Honfleur and most of the towns which I visited similar inequalities will be found. What, for instance, can be more abominable, but it must be confessed more picturesque, than the mediaeval Rue des Rosiers at Rouen? Here the houses are several hundred years old and built in a great measure of wood and stand on redeemed marsh land. The street is very narrow, the houses very high and a central gutter constitutes the main drainage

system At the top of each house, right up in the gable, is a pail. What is not put in this pail—and the pail is not often emptied—goes to the gutter in the centre of the street or sinks into the earth before reaching the gutter. Here and in the Rue du Mouton, which is a continuation of the same street, there have been, in proportion, the greatest number of cases of cholera. The pavement is rough, is saturated with filth, the houses are inhabited by very poor people and over-crowded. The same sort of description would apply to the slums of Honfleur. The very poor court, appropriately named l'Allée des Soupires consists of houses where rooms are hired for 7s and 8s a month where there is no drainage, but stones with dirty water between. The rooms are devoid of proper light and overcrowded. In one dark room I found five persons living together, one being an old invalid woman who had not left her bed for twenty two years. The Pépinière Court at Honfleur consists of old mediæval houses with upper storeys that nearly touch each other across the narrow street. The doors hardly five feet high, are very small, the windows are small, the walls out of line, some bulging forwards as if the houses were about to fall. The earth is black mud oozing out between loose stones, it is all very picturesque, very dirty, very unwholesome, and constitutes a suitable home for cholera.

Speaking to the various authorities, they all maintained that they had no powers to make the owners or occupiers of the houses construct drains. If street gutters were cemented so that the water in them could not sink into the subsoil, and if the subsoil of the houses was protected by laying water tight drains in the houses to carry the slops to the street gutter, there would thus be cheaply established an open air system of drainage which, whatever might be its inconveniences, would in any case protect the subsoil from contamination. This much at least could be very rapidly accomplished. It could be done in time for next spring, and by thus protecting the soil under the houses it is probable that a very important step would have been taken towards protecting the lives of the people living within the houses. If the local authorities really have not the power to act in this sense, the Government should immediately contrive to give the municipalities the means of removing such palpably insanitary conditions.

THE CONFERENCE ON CHOLERA IN ST PETERSBURG

(FROM OUR SPECIAL CORRESPONDENT)

THE conference of Russian physicians summoned to the capital to discuss the recent epidemic of cholera and the measures to be adopted to cope with a renewed outbreak next summer held its first meeting on Sunday, Dec 13th (25th). The conference would perhaps be more correctly described as a Government Commission, the members have been selected by the Government or its local representatives, and the meetings are held with closed doors. As already stated previously,¹ each Government or province throughout the empire is represented by one or two medical men selected for the closeness of their personal experience of the epidemic. These official members number about 150, the remaining members of the Conference being representatives of the Ministries of the Interior or War of Finance and of Wars and Communications, the president and members of the Medical Council, the professors of the Army Medical Academy, the National Health Society, the senior physicians of all the St. Petersburg hospitals and the students who took part in the struggle with the epidemic.² The total number of members was thus brought up to nearly 300. The meetings of the Conference have taken place each evening in the Michael Palace, kindly lent for the purpose by the Grand Duchess Catherine Michaelovna. The sub-committees have met daily from 10 till 3 in the Medical Department of the Ministry of the Interior. The meetings, as already stated, have been quite private, no one not an actual member of the Conference being permitted to be present. The Director of the Medical Department has however,

kindly furnished me with copies of some of the more important communications, a brief summary of which may be of interest.

The Conference was opened by a speech from the Minister of the Interior, M. Durnovo, who welcomed the members and expressed the thanks of the Government for their self sacrificing activity in the struggle with the epidemic.

Dr. Ragozin, the Director of the Medical Department and President of the Conference, gave an introductory address on the work to be done by the members and was followed by Dr. Grebentschikoff, the head of the statistical division of the medical department, who read an important paper on the statistical data of the epidemic and its mode of propagation. The present epidemic, he said, is a continuation of a pandemic which began its course in 1881 and has since then spread to almost every country of the Old and New World. Starting in Hedjaz (the province of Arabia which borders the Red Sea), the cholera was carried by Mussalman pilgrims and in 1883 reached Lower Egypt, Syria and Mesopotamia on the one hand, while on the other the disease was spreading from its endemic centre in India to China and Japan. In 1884 it passed from Egypt to the northern shores of the Mediterranean Sea, affecting more particularly Toulon, Genoa, Naples and the Spanish province of Alicante, penetrating to Algiers and at the same time continuing its ravages in Japan. In 1885 cholera raged in Arabia, Syria, Mesopotamia, Egypt, Italy, France, Spain and Japan, and in 1886 it appeared in each of these countries and in Germany (Mayence), Austro Hungary, and in the New World in the Argentine Republic and Chili. In 1887 having disappeared almost entirely in Europe and become much less severe in Turkey in Asia, South America and Japan, cholera appeared in Malta for the first time during the present pandemic, and also in New York. In 1888 it reappeared in Italy and Austro-Hungary continued in South America, China and Japan, and appeared in the Philippine Islands (East Indies), and in Vladivostok (Eastern Siberia). In 1889 cholera was present in the Sunda and Philippine Islands, in Turkey in Asia, China, Japan, and also in Persia. In all these countries it remained for two years, and in 1890 attacked in addition the Corea, Vladivostok, Siam, Ceylon and Massowah. Finally, in the present year it crossed from Persia into Russia, and has since spread to Germany, Austro Hungary, Belgium, Holland and France.

(To be continued)

THE DRAINAGE OF MIDDLE-CLASS DWELLINGS

It is only too probable that cholera may be brought over to England next spring. Will it take root in this country? Now is the time when everybody should put his house in order, it will be too late when once the epidemic is upon us. A great deal has been done with regard to the homes of the poor. These may be dirty and overcrowded, but there are not those vices of construction which still prevail—and this to an alarming extent—in middle-class dwellings. What with official and amateur sanitary inspection, the habitations of the poor are technically speaking often in a much better sanitary condition than those of the middle classes. For instance, a great portion of the working and poorer classes live in small cottages, with open space back and front, and with no closets or dustbins indoors. Even the scullery and the sink are in an outhouse. In fact, in many instances there is no drainage whatsoever within the dwelling portion of the cottage. The middle class houses have, on the contrary, their closets, their sinks, their bath pipes &c., indoors, and all these are sources of danger if they are not perfect in structure and ventilation. No philanthropists visit these middle-class dwellings to see if they are in a good condition, the sanitary inspector only comes if called or if there be an outbreak of infectious disease. Perhaps it may be said that the inhabitants are well enough educated and sufficiently intelligent to look after their own sanitation. Such unfortunately is not always the case, and where there is a disposition to set matters right there are often financial and other reasons which prevent the realisation of these good intentions.

Undoubtedly great care has been bestowed on the drainage

¹ Vide THE LANCET Dec. 10th 1892.

² A considerable number of fifth year students were sent from St. Petersburg and from the University of Kharkof to the infected districts more particularly to the country of the Don Cossacks and to the Caucasus.

of the more modern middle class dwellings. After all it does not cost more to drain well than to drain badly, but the details of good domestic drainage were not known to the generality of builders some twenty or thirty years ago. Consequently it is very probable that more than half the middle class houses of London have defective drainage. Let us take houses with rents varying from about £30 to £100 a year. On entering the hall the staircase generally rises straight up in front. Passing by the parlour, we probably find a closet under the stairs. This closet very often has no ventilation. It has an opaque glass door and receives a little light from the window in the passage. If the wall of the closet is not against the wall of the next house, then, perhaps, one single brick has been removed and this small hole is called ventilation. In this latter case there is no reason why the hole should not be enlarged and converted into a window of at least eighteen inches square. But in the frequent instances where the wall cannot be pierced the closet must be removed and placed in front of the side window which as a rule faces the closet door. This may darken the passage, but that is preferable to ventilating the closet into the passage and the house. The closet on the first floor is likely to be better situated and to have a window, but the basement closet is often as badly placed as that under the stairs on the parlour floor. Then, when we proceed to examine the closets, it will be found that the old fashioned D trap and pan container are still largely in use. Though in every text book on sanitation this form of closet is unanimously condemned it is nevertheless still employed throughout the country. Then, again, these closets which can never be clean and never free from unpleasant odour, are supplied with water direct from the cistern. They have no water-waste preventers, but are connected directly with the cistern from which the drinking water is derived. Often these cisterns are so placed that they cannot be easily reached and are consequently but rarely cleaned. Finally, there are the drain pipes, which especially in jerry built houses are laid down so carelessly that they leak at the joints.

Undoubtedly, in view of the probable cholera epidemic, every drain pipe in England should be tested at once. There are contrivances that can be thrown down and will promptly disclose the existence of a leakage, or else anyone can get some oil of peppermint and, mixing it in a bucketful of warm water throw it into the highest closet. Where sewer gas escapes through the drains there the odour of pepper mint will also be detected. If this experiment were made in every home we fear that an appalling number of houses would be found to have leaking drains.

There is much evidence to show that the condition of the subsoil has great influence in determining the spread of cholera epidemics. Apparently if the subsoil is contaminated by a numerous population living on a spot inefficiently drained, there is a greater local susceptibility to cholera. What, then, will be the condition of dwellers in houses where

the subsoil has for years been contaminated by the leakage from badly laid drain pipes? To cite but one out of many illustrations of this danger, M. Guérard, civil engineer, in his report on the great cholera epidemic of Marseilles in 1884, describes how in the poorest dirtiest quarters of the town there were some streets almost entirely exempt from cholera. These streets only differed from the neighbouring streets inasmuch as they had sewers, consequently the slops and dirty water from the houses flowed rapidly away instead of sinking into the subsoil. But in England the slop and dirty water from the houses, instead of going at once to the sewer too often in part escapes through leaking drain pipes into the subsoil immediately under the houses. In such cases it is not only necessary to dig up and relay faulty drain pipes, but the surrounding soil, which will be found in a filthy condition, must also be carried away and clean gravel put in its stead.

The urgency of immediately taking all these measures cannot be denied, and yet there are many practical difficulties to be overcome. Many occupants of middle-class houses dare not in any way vex their landlords. Many pay their rents irregularly, others could not afford to remove, and for many personal and financial reasons would be very reluctant to cause their landlords any inconvenience. The landlords themselves are often in anything but an enviable position. They have invested their money in houses, imagined these houses to be in a good condition and have rented them on certain terms. Now they may be called upon to spend £50 or £100 to redrain these houses. This may equal the loss of a year's rental or income. Of course every effort will be made to avoid such a sacrifice. Thus, what with tenants who do not like to trouble their landlords, and landlords who, as investors and speculators in house property, are sailing rather near the wind and therefore cannot afford to undertake large, unforeseen and expensive sanitary improvements, the causes of unsalubrity described above are likely to remain unaltered. No general improvement will be effected unless sanitary authorities intervene. Here and there a liberal landlord or an enlightened tenant, possessing special knowledge of these questions and fully impressed as to their importance, may bring about the necessary alteration during the course of this winter. In the great majority of cases nothing will be done unless pressure is brought to bear by outside and disinterested persons. The best thing would be for each local authority to at once undertake a house-to-house visitation and do their utmost to compel those responsible in each case to relay the drains where leakage is detected, to provide inlet and outlet ventilation for the drains, to remove all D traps and pan containers to place the cisterns where they can be easily inspected and cleaned and to provide each closet with a separate water waste preventer flushing cistern. If this were done, and done at once, we might view with but little anxiety the recrudescence of cholera next spring.

THE LANCET RELIEF FUND

FOURTH ANNUAL REPORT OF THE ALMONERS

THE LANCET Relief Fund, which has for its Almoners the President of the Royal College of Physicians (Sir ANDREW CLARK, Bart., FRS) the President of the Royal College of Surgeons (Mr THOMAS BRYANT) the President of the General Medical Council (Sir RICHARD QUAIN, Bart., FRS), Mr THOMAS WAKLEY, FRCS, and Mr THOMAS WAKLEY, jun. LRCP Lond., with Sir HENRY PITMAN, MD Camb, FRCP, as Honorary Auditor, came into operation on the 1st of February, 1889.

In presenting the fourth annual report, the Almoners think it well again to direct attention to the objects for which the Fund was established.

For the sustentation of the Fund the sum of at least £300 will be provided every January by the Proprietors of THE LANCET, and administered free of cost for the purpose of affording immediate pecuniary assistance to registrable medical practitioners, or to the widows or orphans of members of the profession in cases of distress and emergency by the grant of money by way of loans free of interest or gifts as the circumstances of the various cases may require.

When the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had

been established, and as a result the majority of the earlier applications being cases of *chronic* distress, and not coming therefore, under the designation of *emergency*, could not be entertained. Attention was called to this fact in THE LANCET of Feb 16th, 1889 in the following words—

'We are requested by the Almoners to state that, from the character of a number of the applications received both personally and by letter for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood, and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registrable medical practitioners, or to the widows or orphans of members of the profession who in consequence of the supervention of some unexpected exigency which is not likely to recur, have pressing need of immediate and temporary pecuniary relief,' and who, it

system At the top of each house, right up in the gable, is a pail. What is not put in this pail—and the pail is not often emptied—goes to the gutter in the centre of the street or sinks into the earth before reaching the gutter. Here and in the Rue du Mouton, which is a continuation of the same street, there have been, in proportion, the greatest number of cases of cholera. The pavement is rough, is saturated with filth, the houses are inhabited by very poor people and over-crowded. The same sort of description would apply to the slums of Honfleur. The very poor court, appropriately named 'Allée des Soupires' consists of houses where rooms are hired for 7s. and 8s. a month where there is no drainage, but stones with dirty water between. The rooms are devoid of proper light and overcrowded. In one dark room I found five persons living together, one being an old invalid woman who had not left her bed for twenty two years. The Pôpinère Court at Honfleur consists of old mediæval houses with upper storeys that nearly touch each other across the narrow street. The doors, hardly five feet high are very small, the windows are small, the walls out of line, some bulging forwards as if the houses were about to fall. The earth is black mud oozing out between loose stones, it is all very picturesque, very dirty, very unwholesome, and constitutes a suitable home for cholera.

Speaking to the various authorities, they all maintained that they had no powers to make the owners or occupiers of the houses construct drains. If street gutters were cemented so that the water in them could not sink into the subsoil, and if the subsoil of the houses was protected by laying water tight drains in the houses to carry the slops to the street gutter, there would thus be cheaply established an open air system of drainage which, whatever might be its inconveniences, would in any case protect the subsoil from contamination. This much at least could be very rapidly accomplished. It could be done in time for next spring, and by thus protecting the soil under the houses it is probable that a very important step would have been taken towards protecting the lives of the people living within the houses. If the local authorities really have not the power to act in this sense, the Government should immediately contrive to give the municipalities the means of removing such palpably insanitary conditions.

THE CONFERENCE ON CHOLERA IN ST PETERSBURG

(FROM OUR SPECIAL CORRESPONDENT)

THE conference of Russian physicians summoned to the capital to discuss the recent epidemic of cholera and the measures to be adopted to cope with a renewed outbreak next summer held its first meeting on Sunday, Dec. 13th (25th). ² A considerable number of fifth year students were sent from St. Petersburg and from the University of Kharkof to the infected districts, more particularly to the country of the Don Cossacks and to the Caucasus.

FORRES LEANCHOIL HOSPITAL

THIS cottage hospital has been constructed for Forres and the surrounding district, which has a population of upwards of 10,000, the town population being about 5000. The hospital owes its erection mainly to the munificence of Sir Donald A. Smith, K C M G, LL D Camb, a native of Forres but now of Montreal, Canada.

The designs for the building, originally planned by the late Mr John Rhind of Inverness, were submitted by the managers to Mr H. Saxon Snell to report upon, but in consequence of the decease of Mr Rhind before the working drawings were in hand, Mr Snell was asked to make

some distance in the rear of the present building it is proposed to erect at some future time a pavilion for fever cases as shown above by the small bird's eye view.

Accommodation is provided in the building now erected for 12 patients. The larger wards, containing 4 beds each, are 24 feet long by 20 feet wide and 13 feet high, giving a superficial area of 480 feet, or about 120 feet per bed, and a cubic space of 6240 feet, or 1560 feet per bed. The smaller wards for 2 beds each are 13 feet long by 20 feet wide, giving a superficial area of 260 feet or 130 feet per bed, and a cubic space of 3380 feet, or 1690 feet per bed. The lineal wall space given to each bed is 12 feet in the larger and 13 feet in the smaller wards.

The wards are warmed by ventilating stoves specially designed for the building with inlets through the walls for the admission of fresh air to them. The dry rooms and

such modifications in the design as he thought desirable and to superintend the carrying out of the work.

The principal entrance to the hospital is through the centre of the front block, a two-storey building containing on the ground floor the matrons and surgeons' rooms, operating room, kitchen and offices, and on the first floor bedrooms for the matron and nurses. At each side of this central building and separated from it by the connecting corridors hereafter referred to are blocks one storey high, containing the sick wards, each having one ward for the accommodation of four beds, and another for two beds. Behind the central block is a one storey building containing the laundry and also the mortuary and ambulance shed. At

corridors are warmed by "Galton stoves." Fresh air is admitted to the wards through the stove casings, in which it is warmed, and through air shafts in the walls which have adjustable hopper arrangements for the admission of the air at a height of 10½ feet to the under side of the hopper above the floor, by means of which the air has an upward impulse imparted to it which tends to prevent its sudden descent as a draught. These hoppers, of which there is one to each bed, can be closed at will. The foul air has its exit through ventilators in the roof.

The floors are of ordinary joisting with hard Canadian maple flooring in 3 in. widths, wax polished and with deal counter floors between them and the joisting.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH.

County of Surrey—Dr Seaton, the county health officer has issued a somewhat voluminous report much of which has mainly a local interest. He points out that there has been great improvement in the preparation of the statistical returns by the several medical officers of health, and he tabulates these at length. But he does not think that the statistics as yet cover a sufficient term of years to justify his drawing deductions from them. Dr Seaton has held no less than thirty-six conferences with a view to securing isolation hospitals for the county but we believe that with one exception no substantial advance has as yet been made in this direction. In an appendix are included the analyses of the several local reports and it is stated that Dr Seaton's own report on the county will appear as a separate document.

West Sussex Combined Districts—This well known combination of sanitary districts which is under the care of Dr Charles Kelly now contains a population of over 106,000, it had, as a whole, during 1891 a birth rate of 27.8 and a death rate of 16.4 per 1000 living, the latter rate not taking

account of visitors to such places as Worthing and Little Hampton. The zymotic rate was 1.5 per 1000 and it is stated that by the addition of the Horsham urban district at the end of last year the compulsory notification of infectious diseases is now universal throughout the combined area. Dr Kelly's report, which covers no less than 215 pages deals separately with each of the eleven sanitary districts involved, and the vital statistics are considered in some detail both for the district as a whole and for each of its constituent parts.

Basford Rural District—Dr James S Tew reports that during 1891 the general death rate was 16.4 per 1000, and he discusses the various aspects of the vital statistics at some considerable length. Referring to the notification of infectious diseases he laments the absence of means of isolation but he states that even with this drawback and with the added one of an insufficient inspectional staff a large number of instances have been brought to light by the aid of notification which have admitted of the application of valuable remedial measures. No less than 252 cases of scarlet fever with nineteen deaths took place and the prevention of the disease was much hindered by the absence of a hospital. Improvements are in progress as to water-supply drainage works which need to be pushed, are at least under consideration. Public scavenging is on the whole a distinct success, and the current work of the district is evidently as well maintained and as well supervised as is practicable with the existing staff.

County of Renfrew—Dr Campbell Munro's first annual

may once more be pointed out, are likely to be permanently benefited thereby

The balance in hand at the end of 1891 amounted to the sum of £170 14s. On January 5th, 1892, the Proprietors of THE LANCET placed to the credit of the Fund the sum of £300. During the course of the year repayments to the amount of £5 have been made. The sum of £304 has been granted in relief either by way of loan or of gift, leaving a balance of £171 14s.

There have been considered altogether during the twelve months ending Dec 31st, 1892, 34 applications for relief (the number the previous year having been 27). In 19 cases assistance was afforded, either as a loan or as a gift, according to the request of the applicant, the amounts of the grants ranging from two pounds (given on a special occasion and for a special purpose) to £50.

The following are extracts from a few letters received from some of the recipients of the Fund —

CASE 120 — "Your kind gift from THE LANCET Fund I have safely to hand, and beg to tender my most grateful thanks for the kindness shown unto me in this my heavy bereavement."

CASE 121 (husband hopelessly insane) — "I beg to acknowledge the receipt of cheque for £25 from the Almoners of THE LANCET Fund, and I wish to express my most sincere and grateful thanks for this extreme benevolence and kindness. This timely assistance will indeed place me in a position enabling me to support our young family, and I do indeed most deeply appreciate this generosity. Should I ever be sufficiently successful in business to be able to do so, it will be my greatest desire to prove my gratitude for the present kindness by contributing to the Fund."

CASE 122 — "The substantial and prompt help which the Almoners have so benevolently accorded will prove of essential service in his great need. I called upon Dr. — to day and he begged me most earnestly to thank the Almoners for their kind and acceptable gift."

CASE 129 — "I thank the Almoners for their great kindness in granting me the loan, for which I enclose receipt. I can assure you it has come at a most opportune time, and I have no doubt will be a lasting benefit to me."

CASE 136 — "I beg to return my most sincere and heartfelt thanks for the gift of £15 and loan of £15 accorded to me by the Almoners of THE LANCET Relief Fund. This kindness will be a great boon in present circumstances and I shall ever feel grateful for it."

CASE 139 — "Although Mr. — continues to improve satisfactorily he is not equal to writing, therefore asks me to

do so for him to acknowledge your very kind letter received this morning with cheque for £20, kindly sent to him as a gift by the Almoners of THE LANCET Relief Fund in his great need and feeble health. No words of his or mine can sufficiently express the deep gratitude we both feel for the great goodness extended by them to us, and we can only hope and pray that our Heavenly Father may return it to each of them individually tenfold, for it is indeed a most noble and Christian act."

CASE 147 — "Will you please express my best thanks to the Almoners of THE LANCET Relief Fund for their goodness in granting me a gift of £10. I feel very grateful to them, it will help me and my children very much at the present time."

CASE 144 — "I received your kind letter with cheque for £10 enclosed, for which I beg you will convey to the Almoners my sincere thanks. It has indeed come at the time when I most needed it to enable me to still keep my house and home together. I trust God will reward those who have so kindly helped me in the time of need. The £10 will now enable me to keep on the house and have all my furniture saved."

CASE 149 — "I beg to acknowledge the receipt of £10 and request you to kindly convey to the Almoners my most sincere thanks. I owe them a debt of everlasting gratitude as I shall now be able to make a fresh start in life."

CASE 150 — "Allow me to tender my sincere thanks to the Almoners of THE LANCET Relief Fund for the gift of £5. Indeed it was extremely kind of them to help a foreigner in distress far from his kindred. You can imagine better than I can express my heartfelt gratitude for their kindness."

It will be observed that Case 121 speaks of her desire to prove her gratitude by (if possible) at some future time contributing to the Fund. During the course of last year the Almoners received a cheque which a medical practitioner kindly forwarded as a donation to the Fund. This of course had to be returned with expressions of thanks and regret that the Almoners were unable to avail themselves of the contribution. It may be well therefore to direct attention to the fact that the means of sustentation of the Fund are provided solely by the Proprietors of THE LANCET. The Secretary of the Fund is Mr. Edward Davies, to whom all communications should be addressed.

I find by the Bankers' Book that the actual balance on Jan. 1st, 1892, to the credit of the Fund was £170 14s., to which the sum of £300 was added by the Proprietors of THE LANCET on Jan 5th, 1892.

The balance at the Bankers at the present date is the sum of £171 14s. I have also checked the receipts for disbursements and find the above account strictly accurate.

December 30th, 1892

HENRY A. PITMAN Hon Auditor

increased to 17 last week and included 13 in Glasgow. The 9 fatal cases of diphtheria corresponded with the number in the previous week and included 6 in Glasgow. The deaths from scarlet fever, which had been 18 and 13 in the preceding two weeks, further declined to 7 last week, of which 5 occurred in Glasgow and 2 in Leith. The deaths referred to diseases of the respiratory organs in these towns which had been 193 and 163 in the preceding two weeks, rose again last week to 212 and exceeded by 9 the number in the corresponding week of last year. The causes of 49 or more than 6 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had increased from 22.8 to 25.7 per 1000 in the preceding five weeks, further rose to 33.4 during the week ending Dec. 31st. During the thirteen weeks of the last quarter the death rate in the city averaged 24.4 per 1000 against 19.4 in London and 23.9 in Edinburgh. The 224 deaths in Dublin during the week under notice showed an increase of 45 upon the number in the preceding week, and included 5 which were referred to diarrhoea, 4 to "fever," 2 to whooping-cough, 1 to measles and not one either to small pox, scarlet fever, or diphtheria. In all, 12 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.8 per 1000, the zymotic death rate during the same period being 2.2 in London and 3.5 in Edinburgh. The fatal cases of diarrhoea, which had declined from 3 to 1 in the preceding three weeks, rose again to 5 last week. The deaths referred to different forms of "fever," which had increased from 2 to 9 in the previous three weeks, declined to 4 last week. The 2 fatal cases of whooping-cough exceeded the number recorded in any recent week. The 224 deaths registered in Dublin last week included 25 of infants under one year of age and 71 of persons aged upwards of sixty years, the deaths of infants showed a slight further increase, and those of elderly persons considerably exceeded those recorded in any recent week. Thirteen inquest cases and 7 deaths from violence were registered, and 80 or more than a third, of the deaths occurred in public institutions. The causes of 15 or nearly 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES

MOVEMENTS OF MEDICAL STAFF

Surgeon Captain Beatty has arrived at Sierra Leone and **Surgeon Captain McLoughlin** has left for England. **Surgeon Captains Mills and Squire** have left Madras on completion of their tour of service. **Surgeon Major Emerson** and **Surgeon Captain Robinson** have obtained leave from Madras and **Surgeon Lieutenant Colonel Macrobis** has been transferred to Kassaul. **Surgeon Lieutenant Colonel Bridges** has obtained leave of absence from Weedin and **Surgeon Major Hodson** from Portsmouth. We understand that **Surgeon Colonel T. Maunsell** will probably be appointed to fill the caused vacancy in India by the death of **Surgeon Colonel Godwin**.

ARMY MEDICAL SERVICE

Surgeon Colonel Preston has been selected for the appointment of **Principal Medical Officer for the China Station** and leaves shortly for Hong Kong.

MILITIA MEDICAL STAFF

Surgeon Lieutenant Colonel Sir William Miller, Knt. M.D. the London Artillery (Southern Division, Royal Artillery) retires with permission to retain his rank and to wear the prescribed uniform on his retirement (dated Jan. 4th, 1893).

INDIA AND THE INDIAN MEDICAL SERVICES

The undermentioned **Surgeon Lieutenants** appointed to the Bengal Establishment reported their arrival at Bombay on Nov. 1st, 1892—**Patrick Balfour Haig**, **Thos. Wm. Archer Ballerton**, **Ralph Henry Maddox**, **Harry George Melville**, **Arthur Oldham Hubbard**, **Herbert Austen Smith**, **George McIver Campbell Smith** and **Joseph George Hulbert**. The undermentioned officers have returned from furlough out of India—**Squadron Officer M.L. Surgeon Captain G. C. Hall, I.M.S.**, and **Surgeon Captain P. C. H. Strickland, I.M.S.** Under instructions from Army Headquarters, India, it is notified for information that the under-

mentioned officer of the Army Medical Staff, expected from England for duty in India, has been posted to the Bombay Command—**Surgeon-Major J. Fitzgerald Brodie**, in augmentation of establishment. **Medical Staff-Surgeon Captain R. Holvoake** has been granted leave to remain in England from Nov. 26th, 1892, to May 25th, 1893, in extension of the leave **Surgeon-Captain H. W. Elphick**, Officiating Civil Surgeon, on being relieved by **Surgeon-Captain W. G. P. Alpin**, has been transferred from Ghazipur to Muzaffarnagar. **Surgeon Major A. F. Ferguson, M.B., C.M.**, has been appointed to act as Civil Surgeon, Shikarpur, and **C. J. Sarkis, M.B., C.M.**, to act as Civil Surgeon, Ahmednagar in addition to his own duties, during the absence of **Surgeon Major W. G. H. Henderson, F.R.C.S.I.** **Veterinary Lieutenant G. H. Evans** is appointed to the Civil Veterinary Department on probation and posted to Burma. **Surgeon Captain J. G. Jordan**, Officiating Civil Surgeon of Jessore, is appointed to act as Civil Surgeon of Noakhali, during the absence, on deputation, of **Surgeon-Lieutenant Colonel Kahl Pada Gupta**, or until further orders. This cancels the notification of Nov. 22nd, 1892, appointing **Surgeon Major G. Shewan** to officiate as Civil Surgeon of Noakhali. **Surgeon Captain P. W. O. Gorman** is appointed to act as Civil Surgeon of Jessore. **Surgeon Lieutenant-Colonel E. Bovill**, Officiating Civil Surgeon of Murshidabad, is appointed to officiate as Civil Surgeon of Shahabad during the absence, on leave, of **Surgeon Major R. Macrae**, or until further orders. **Surgeon Lieutenant Colonel S. L. Dobie, I.M.S.**, Superintendent, Lunatic Asylum, Madras, is appointed to act as Principal Medical Storekeeper, Madras during the employment of **Brigade-Surgeon-Lieutenant Colonel D. F. Bateman** on other duty. The services of **Surgeon-Major T. R. Macdonald**, Superintendent of the Nagpur Central Gaol, are placed permanently at the disposal of the Government of Bengal. **Surgeon-Colonel John Chas. Morice**, Principal Medical Officer, Presidency District, has been permitted to retire from the service from Oct. 24th, 1892, subject to Her Majesty's approval.

NAVAL MEDICAL SERVICE

Fleet-Surgeon Joseph Wood, M.D. has been placed on the Retired List of his rank at his own request.

VOLUNTEER CORPS

Artillery Surgeon-Lieutenant M. Mackenzie to be **Surgeon-Captain** (dated Jan. 4th, 1893)—**1st Gloucestershire Surgeon-Lieutenant-Colonel F. P. Lansdown** resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement (dated Jan. 4th, 1893).

On Dec. 14th, 1892, the third levée of H.E. Lord Harris, G.C.I.E. was held in Bombay. Among the 624 presentations made were the following members of the medical profession—**Arnott**, **Brigade Surgeon-Lieutenant Colonel Banks**, **Brigade-Surgeon Lieutenant-Colonel Boyd, H. W.**, **Surgeon-Major Child**, **Surgeon Captain Crimmin**, **Surgeon Captain Cliffe**, **Surgeon R.N.**, **Dev J. Surgeon Major Dimmock**, **H. P.**, **Surgeon Major Edmonds**, **G. Surgeon R.N. Fooks**, **Surgeon Major Gravfoot**, **Surgeon-Captain Herbert**, **H. Surgeon-Captain I.M.S.**, **Hajel**, **Surgeon Captain I.M.S.**, **MacCartie**, **Surgeon Major Maconachie**, **G. A.**, **Brigade Surgeon-Lieutenant Colonel Mills**, **J.**, **Veterinary Surgeon A.V.D.**, **Meyer**, **Surgeon Captain Parker**, **J. Surgeon Major Piddle**, **Surgeon Lieutenant-Colonel Underwood E.T.**, **Dr. Waters G.**, **Surgeon Lieutenant Colonel**.

ARMY MEDICAL CHANGES

Under the above heading our contemporary the *Army and Navy Gazette* has some remarks on the difficulties that exist at present in arranging for the various changes and relief at home and abroad, and is of opinion that much of the disturbance of personnel might have been avoided if the original warrant had been adhered to and extension or service had only been granted when it was distinctly required in the interest of the public service and the officer had in such cases been seconded. In two years about thirty out of thirty-four administrative officers will have changed stations. We cannot believe that there is any foundation for the rumour that the present principal medical officer at Gibraltar will be brought home from that station to fill a vacancy that will occur in the Director General's office at home. We need scarcely reiterate what we have so often said—viz. that, in our opinion, any extension of service in the administrative grades should be quite exceptional and that the officer so extended should be seconded. Any other system can only prove very unfair to

report on the health and sanitary condition of the county of Renfrew is, as it should be, a very complete and exhaustive document. It enters fully into all the various health and other allied considerations affecting the county, and it may be taken as intended to serve as the basis for future work, and as affording a means by which comparison can be made in the future between what now exists and that which will be brought about as the result of a careful and skilled sanitary administration. The county starts with substantial means for the isolation of the infectious fevers, and it has local advantages in being a well watered district, which should lead to the abandonment of existing suspicious supplies in favour of wholesome and properly delivered services. Drainage is a subject which will involve much labour, especially in connexion with the existing pollution of streams and the actual circumstances of individual localities and villages. The state of the county as regards infectious diseases having been considered, the several administrative questions involved in such matters as dairy inspection, control of slaughter-houses, bakehouses and common lodging houses are discussed, and a series of tables together with a disease chart are appended. The report, in fact, is typical of what such an initial report should be.

Halifax Urban District—Mr Ainley records a death rate of 22.6 per 1000 during 1891, the corresponding zymotic rate being 1.91. The infantile mortality for children under one year of age gave a death rate of 172 per 1000 births. This is excessive, but it hardly seems related to factory labour by mothers, for of 660 deaths under five years of age, the mothers were in 517 cases engaged in domestic work at home only 50 having to leave their homes for any kind of labour. A new infectious hospital has not been decided on and 111 cases were admitted into the existing one during the year. Good work has been undertaken as regards artisans' dwellings and house-to-house inspection is maintained. But improvement is strongly called for with respect to the removal of house and other refuse.

Fulham Parish—This district had a general death rate of 19.7 during 1891. The cases of notified disease were 330 in number, and of these 73 were cases of diphtheria and 55 of enteric fever. These notifications led to a large amount of remedial work as regards drainage nuisances &c. The report deals very largely with general questions, such as memoranda of the Local Government Board and conferences of health officers on the subject of the Housing of the Working Classes Act, 1890, but it also contains a good deal of information as to the principal sanitary circumstances of Fulham and as to its wants. The record given by Mr Cooney as to powers, duties and modes of action to secure amendment as regards unhealthy areas and dwellings is a useful one for local purposes.

City of Dublin—Omitting deaths of persons in public institutions who came from places outside the city, the death rate during 1891 was 25.5 per 1000. Sir Charles Cameron points out that whilst typhus fever has almost disappeared from Dublin, enteric fever shows no tendency to decline. A mean of some 42 deaths from this cause occurred annually from 1881 to 1888, then the number rose to 71 in 1889 it was 47 in 1890 and in 1891 it reached no less than 172. The causes of this maintained prevalence are held to be obscure but pollution of subsoil and defective means of drainage in the case of a city built on a waterlogged site are set out as prime factors, and Sir Charles Cameron seems convinced that the city water collected from so sparsely populated a catchment area cannot be at fault, neither is any evidence suggested as to the possibility of pollution of some main water carrier, whether running full or not. The whole subject of the etiology of enteric fever is fully discussed in the volume, which has in consequence considerable interest.

County of Lancaster—Mr Sergeant has issued a somewhat voluminous report on this county during 1891, the volume containing summaries of all the local health officers' reports. Comparative statistics are displayed in a way that must have local value, and the incidence of the several infectious fevers in the different portions of the county is considered in some detail. Notification is now in operation in seventy urban and fifteen rural districts, but hospitals for infectious diseases are much needed and it is evidently Mr Sergeant's opinion that such hospitals, to be of real use, must keep their ordinary wards free in so far as cost to those occupying them is concerned. In replacement of the old midden privy system we find that the pail system, waste water closets and the ordinary water carriage system are in a number of places gradually coming into operation. Questions of scavenging, water supply,

sewerage &c. are discussed under several headings, and it can hardly be that such comparative data as are afforded by the local sanitary authorities without serving as a stimulus to those who see that satisfactory results have followed in those districts where most sanitary progress has been made.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

In thirty three of the largest English towns 5293 births and 4751 deaths were registered during the week ending Dec. 31st. The annual rate of mortality in these towns, which has been 20.7 and 20.0 per 1000 in the preceding two weeks, rose again last week to 24.3, a higher rate than in any week since March last. In London the rate was 22.4 per 1000, while it averaged 25.7 in the thirty two provincial towns. The lowest rates in these towns were 15.7 in Croydon, 16.2 in Huddersfield, 17.5 in Portsmouth and 17.8 in Burnley; the highest rates were 31.9 in Liverpool, 32.0 in Blackburn, 34.0 in Salford and 34.1 in Manchester. The 4751 deaths included 473 which were referred to the principal zymotic diseases, against 448 and 383 in the preceding two weeks, of these, 168 resulted from measles, 103 from whooping-cough, 73 from diphtheria, 54 from scarlet fever, 36 from diarrhoea, 36 from "fever" (principally enteric) and 3 from small pox. No fatal case of any of these diseases occurred last week. Burnley, Huddersfield and Halifax, in the other towns, caused the lowest rates in Derby and Wolverhampton, and the highest rates in Hull, Cardiff, Brighton, Nottingham and Salford. The greatest mortality from measles occurred in West Ham, Cardiff, Bolton, Nottingham, Brighton, Hull and Salford, from scarlet fever in Preston, from whooping-cough in Swansea, Nottingham, Bradford, Portsmouth, Birmingham and Salford, from "fever" in Sunderland and Nottingham and from diarrhoea in Preston. The 73 deaths from diphtheria included 50 in London, 3 in Cardiff, and 3 in Manchester. One death from small pox was registered in Manchester, 1 in Salford, and 1 in Oldham, but not in any other of the thirty three large towns, 39 cases of the disease were under treatment in the Metropolitan Asylum Hospitals and not one in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3254, against 3772, 3626 and 3299 on the preceding three Saturdays, 24 new cases were admitted during the week, against 291 and 241 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 339 to 380 in the preceding two weeks, further rose to 523 last week, but were 90 below the correct average. The causes of 136, or 2.9 per cent., of the death in the thirty three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Bolton, Sunderland, and in five other small towns, the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, Hull and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 25.5 and 24.0 per 1000 in the preceding two weeks, rose again to 28.5 during the week ending Dec. 31st, and exceeded by 4.2 per 1000 the mean rate during the same period in the thirty three large English towns. The rates in the eight Scotch towns ranged from 17.2 in Perth and 18.2 in Greenock to 32.2 in Paisley and 34.9 in Leith. The 793 deaths in these towns included 86 which were referred to measles, 17 to whooping-cough, 9 to diphtheria, 7 to scarlet fever, 7 to diarrhoea, 5 to "fever" and not one to small pox. In all, 131 deaths resulted from these principal zymotic diseases, against 136 and 132 in the preceding two weeks. These 131 deaths were equal to an annual rate of 4.7 per 1000, which was 2.3 above the mean rate last week from the same diseases in the thirty three large English towns. The fatal cases of measles, which had declined from 112 to 86 in the preceding four weeks, were again 86 last week, of which 41 occurred in Glasgow, 15 in Leith, 14 in Edinburgh and 11 in Dundee. The deaths referred to whooping-cough, which had been 5 and 11 in the previous two weeks, further

tion menting social ostracism, the punishment being often specially directed against the fairer members of a deserter's household, who were made to feel that it was little short of criminal to be related to men professing a belief in the pithe cold ancestry of man. Again, the circumstances of the great discomfiture which Owen sustained at the hands of Mr Huxley in their controversy on the relative size of the posterior cornu and hippocampus minor in the brain of man and ape would not have weakened any reluctance which Owen might have felt to joining a camp whose most redoubtable combatant was the author of "Man's Place in Nature." Owen also had been brought up in strictly evangelical principles and would have hesitated long and poignantly before abandoning dogmas and beliefs hallowed by the tenderest associations for the extreme alternative of professing a thorough accord with Darwin, who when asked pathetically in a letter from Lyell, "Have you nothing to say consolatory to the dignity of man?" replied, not in the words of Goethe, "We bid you hope," but in the one word "Nothing." A life and letters of Sir Richard Owen will probably be soon forthcoming to tell us more than we now know of his views on the doctrine of evolution.

I am, Sirs, yours truly,

West Brighton, Jan. 2nd, 1893.

"SOME EFFECTS OF WOUNDS OF THE HEART"

To the Editors of THE LANCET

SIRS,—The annotation under the above heading which appeared in THE LANCET of Dec. 31st, page 1521, brings under notice one of the most important questions in medical jurisprudence and one around which centre many important historical associations. In considering the subject I think the natural division of such wounds is—(1) Wounds of the ventricles and (2) wounds of the auricles, these being subdivided into (c) penetrating and (b) non penetrating. Such an arrangement seems to have been followed by the older writers, commencing with M. Morand, whose work, "Observation sur une Plaque du Cœur," was published in 1735. Garé noticed ("Opera Omnia," liber viii. chapter viii.) that wounds of the ventricle cause death slowly. The great significance of this is dealt with and clearly shown by Beck in his "Jurisprudence." Baron Dupuytren gives Latour's case of 'a ball extracted from the right ventricle near to the apex of the heart, and partly covered by the pericardium six years after the injury was inflicted. William Harvey found a bullet in the heart of a stag. Even wounds that penetrate the auricle are not necessarily suddenly fatal. Dr Grace of Fife's case lasted two days after puncture of the right auricle, and Surgeon Billy's case—wound of the right ventricle—survived five days, the longest period on record that I know of. Death may, however, very suddenly result from the wound for, although the Duc de Berry survived his injury some hours, King Henry IV died almost immediately from the stab of the assassin Ravallac. A very slight puncture of the auricle may quickly cause death. Two such instances are on record (1) The Sardinian nobleman's case, in 1728, at the Court of Victor Amadeus, and (2) that of Admiral Villeneuve, who on April 22nd, 1805, killed himself by piercing the right auricle of his heart with a fine needle. But perhaps the most remarkable case on record is that reported in the *Manitoba Lancet* vol. 1., and copied by me in my article "The Literature of Punctured and Lacerated Wounds of the Heart," in which an attempt was made to remove by operation a needle from the interior of the right ventricle of a medical student. The operation was unsuccessful, but the manipulation of the heart displaced the needle from the position in which it was causing great distress, and for years the patient suffered no inconvenience.

I am, Sirs, yours truly

GEORGE FOX, F.R.C.S.I.

Dublin, Dec. 31st 1892.

"THE TREATMENT OF SEVERE CASES OF CLUB-FOOT"

To the Editors of THE LANCET

SIRS,—The discussion raised by Mr Edmund Owen's paper is a very interesting one and affords an opportunity of once more advocating the forcible correction of club-foot by

1 Medical, Feb 5th, 1893.

means of the Thomas wrench. By this instrument the most intractable cases are materially benefited and, if properly used, there is no occasion for slough or abrasion. I have now treated over thirty cases of the severest types of talipes, in patients whose ages varied from six to twenty three years, with most encouraging results. In some of them I have compared the progress of excision of the astragalus of the one foot with more forcible wrenching of the other. In each case the result obviously favoured the conservative method. By stretching the foot the structures yield in the precise order of their tension and, if carefully performed the skin need never be ruptured. The secret of success lies in the frequent renewal of the effort before the structures have had sufficient time to recover from the strain. Pressure upon suitable splints should be rigorously applied in the intervals between the stretching. It is instructive to note the mobilising power of the wrench. A patient appears with a foot upon which the hand can scarcely make any impression. The wrench is applied, exercised and withdrawn. If it has been effective the surgeon has no difficulty in freely moving the stretched foot into positions which were before impossible. Having had experience of several cases of tarsotomy, I can confidently recommend the routine employment in severe cases of the club-foot wrench.

I am, Sirs, yours faithfully,

Liverpool, Dec. 19th, 1892.

ROBERT JONES.

MEDICAL DEFENCE SOCIETIES

To the Editors of THE LANCET

SIRS,—The steady increase in the number of members of our two medical protection societies shows that many practitioners at any rate have awakened to the importance and usefulness of such societies. I trust in time the numbers now reckoned by hundreds will be reckoned by thousands. I have been a member of one of these societies for about two years, and I think it only right to relate a recent experience of my own as showing that it is not only consultants and general practitioners who may benefit by such membership, but younger members of the profession also, on whom the cares and anxieties of general practice have not as yet descended. I refer to residents in hospitals and other institutions. I am the senior resident here, and on an occasion some time ago had to put outside a drunken patient who was creating much disturbance and declining to leave the premises. He had a child with him—presumably for the purpose of helping him to find the way, he being very drunk—and in going down the steps fell over the child on to the pavement. No complaint of injury was then made, but next day the man appeared again, saying he was suffering from "a fractured wrist and bruised elbow," and wanting to know "what I was going to do for him." On my replying, "Nothing," he said he would make me "pay for it," and the next day I received a solicitor's letter demanding damages and costs under threat of issue of writ. I knew the injuries named could not have been done at the time of the fall, if at all, and I found on inquiry that he had been treated at the Royal Southern Hospital for very slight bruises of the elbow only. I communicated with the Medical Defence Union and by return of post received a reply stating that as the man had declined to leave the dispensary I was quite justified in using reasonable force to put him out and that the Union would be prepared to defend me in any action which might be taken against me. Our solicitor was instructed to write to this man's solicitor offering to accept service of writ on my behalf but from that day to this we have heard nothing more of the case. That is now four months ago, and I am therefore justified in assuming that the attempt has been foiled by the prompt action of the Union.

I am, Sirs, yours faithfully

E PETRONELL MANBY, M.D. Cantab

South Dispensary Liverpool Jan. 2nd 1893.

"ON THE DIAGNOSIS OF THE DIFFERENT FORMS OF PROSTATIC ENLARGEMENT"

To the Editors of THE LANCET

SIRS,—Will you allow me to trespass on your space for the last time by quoting a portion of a letter Mr C Mansell Moullin sent to me in June last when returning my instrument. He says—"I am much obliged to you and am exceedingly pleased with the instrument but I will try some modifications." The logical deductions are obvious,

those officers who are calculating on the promotion to which they would be entitled if the regulations were strictly adhered to

MANLICHER RIFLE BULLET WOUNDS

A Chilean officer, Colonel Talavera, who has been studying medicine, has published as his graduation thesis a study of the wounds inflicted by the Manlicher bullet. His experience leads him to the conclusion that the track made by the bullet through soft parts only has a circular section corresponding more or less exactly to that of the bullet. In these cases there are no foreign bodies found in the track and the wound generally heals without suppuration in from five to ten days. When the end of a long bone is struck a number of splinters are produced and the wound takes a long time to heal. Sometimes, however, the bullet makes a clean perforating wound through the bone and then ten days may suffice for a cure. Where the shaft of a long bone is hit at a short distance the effects may be described as "explosive." When the bullet enters the thorax it sometimes becomes embedded in the lung and remains quiescent there, giving rise neither to an abscess nor to empyema.

THE SCIENTIFIC STUDY OF INDIAN DISEASES

Surgeon Lieutenant Colonel Roe, I.M.S., who has been studying for some time in Paris and Germany, leave having been granted him for that purpose by the Indian Government, has returned to India and proceeds to Sialkot. In Paris he practically investigated the method of inoculating against hydrophobia, and both there and in Germany he studied the latest methods of bacteriological research and inquired into all the latest hygienic improvements introduced into the French and German armies, consequently this officer should be in a position to carry out and apply the results of his labours to the pathological and bacteriological investigation of Indian diseases. It is understood that Surgeon Lieutenant-Colonel Roe has taken a complete bacteriological laboratory with him to India.

THE SICKNESS AT PESHAWAR

According to the last accounts from India the epidemic of fever which has prevailed so extensively of late at this station had shown marked signs of abatement. The ineffective state of the garrison, attributable to sickness at the time of Lord Roberts' visit, is described as something quite exceptional. Officers, non-commissioned officers and men were attacked and the number of soldiers in hospital or on the sick list was unusually large. The British regiments which suffered so much have been removed from Peshawar and a medical inquiry is taking place at present into the nature and causes of the disease.

Correspondence.

"Audi alteram partem"

THE LATE DR WALSH

To the Editors of THE LANCET

SIRS,—Whilst the name of Dr Walsh is still fresh in the memory I should consider it a privilege if you would allow me to occupy a few lines in order to say how thoroughly I can endorse all that his biographer has related of him in your columns. This wish arises from no evanescent feeling aroused by the sorrow of his loss, it having been a life-long conviction with me that, regarded from all points of view, there was no more distinguished man in our profession than Dr Walsh. In the early part of my career, having perused some of his writings and compared them with the looseness and unsatisfactory conclusions of much of the contemporary medical literature, I naturally looked upon him as the "coming man." This opinion grew stronger after the publication of his model books on chest diseases. I was therefore always waiting in expectation of seeing him take not only his right position in the profession, but blazing forth like a luminary as a leading representative of medicine in the world at large. As years went on I never lost my faith, but was forced to add to it grievous disappointment at not seeing my anticipations realised. Personal reasons, such as delicate health, can have been the only cause of the want of recognition of Dr Walsh as one of the great leaders of the profession. I had unfortunately only a slight personal acquaintance with him, but whenever

we did meet I was always charmed. His mental powers were certainly of a very remarkable kind, for he not only had a spark of the heavenly fire of which he speaks in his paper on "Genius," but he was possessed of faculties which rarely accompany it—precision and power of observation, which are the great characteristics of the scientific man. This combination of talents which are generally considered incompatible was present in a most remarkable manner in the case of Dr Walsh. One of your correspondents has called attention to the "Society of Observation" which Dr Walsh founded, and he further gives the names of many of its members now living, he also speaks with uncertainty as to the date of its dissolution and the home of its records. Some of the gentlemen mentioned will be able, I should think, to afford the required information, but if not, assuredly the secretary, Dr Ballard, would be able to do so. Being at present away from home I am unable to verify my statement, but I believe Dr Ballard was the writer or compiler of the little book issued by the Society and entitled "What to Observe." It was quite at the close of the Society's existence that I was requested to join and therefore only attended two or three meetings. This was, if my memory serves me right, in the year 1854. Its dissolution took place from the exigencies of increasing private practice and hospital work required of its members. The Society was the literal exponent of Dr Walsh's views, its object being the obtaining more accurate reports of cases than had hitherto been attempted by noting down every particular, however apparently trivial, and so keeping the mind quite unbiassed by any foregone conclusions. The method, it need scarcely be said, was most irksome, to some it seemed purposeless and often ludicrous. I may mention an example. The human body was divided out with capital letters and subdivided by smaller ones. At one of the last meetings a member was reading a case of some cerebral disease when he came to the big letter signifying abdomen and the little letter signifying bowels, and reported the usual action on that day. He was stopped by the President and asked if he knew this personally as a fact, and the answer being that he was only informed of it by others, he was requested to make a query to this item of the report. The reading went on until the same letter was again reached, when the same statement was made, with the assuring interpolation of the reporter that he saw the patient go to the closet. "But," said Dr Walsh, "did you follow him to obtain accurate knowledge of the result?" This was a little too much for the meeting and roused a general laugh. The method adopted by the President was no doubt the correct one, and the dissolution of the Society would have to be regarded as a loss to medicine did we not know that the system of reporting is now carried on in the most perfect manner at most of the hospitals.

From what I knew of Dr Walsh, and looking upon his varied abilities whilst viewing him in many other aspects, I recognised during his lifetime no greater man in our profession.

I am, Sirs, your obedient servant,

Jan 3rd, 1893

SAMUEL WILKS.

THE LATE SIR RICHARD OWEN

To the Editors of THE LANCET

SIRS,—The admirable leading article on the late Sir R. Owen, and the late Dr Walsh, which appeared in THE LANCET of Dec 24th, makes a brief allusion to his attitude towards Darwinism. It is a puzzling study to endeavour to make out his precise opinion of the great doctrine which has effected, and is effecting, such a stupendous revolution in human thought. When the famous review of the "Origin of Species" appeared in the *Quarterly* from the pen of the late Bishop Wilberforce it was generally considered that the scientific "points" of that truculently hostile essay had been supplied to his lordship by Owen. It appears probable that subsequently Owen's views were considerably modified and that he gave at least a qualified adherence to the new view of life and existence. Many of his contemporaries thirty years ago were somewhat in the state of mind of Carlyle, who cursed Darwin's theory, yet (*pace* Froude) "greatly feared it would turn out true." It is not unlikely that to some extent Owen was under the pressure of influence in a high quarter which was brought to bear on him for the purpose of keeping him steady in the ranks of orthodox theology. Such influence as is here indicated was not unfelt by Sir Charles Lyell and much resentment was shown when that eminent geologist crossed the rubicon and became an avowed supporter of the new doctrine. Such a confession of faith was regarded as deser-

to isolate these cases and to have a separate medical man to attend such. Meantime, the County Lunatic Asylum has written refusing to take lunatics from the Sunderland Workhouse until it can show a clean bill of health.—At the late meeting of the Auckland Guardians the medical officer drew attention to the great hardship of his having to attend a small pox hospital with which his duties were in no wise connected, and to the fact that he had to suffer serious loss in his private practice in consequence. He asked therefore for a substantial increase in his salary if he continued to be identified with the small pox hospital. The subject was left open for further consideration by the guardians.

Cumberland

A deputation from the Trustees of the Town and Harbour of Maryport have waited on the Local Government Board at Whitehall relative to the proposed hospital at Maryport for the isolation of patients suffering from infectious disease. The Trustees are anxious to proceed with the erection of the hospital, and by this interview sought to shorten the preliminaries as much as possible.—Mr J G Wilson of Thistlewood has bequeathed £500 to the Cumberland Infirmary at Carlisle.—It has been decided to erect a new infirmary at Lancaster, the estimated cost of which will be about £17,000.

South Shields and the Inebriate Question

At a late meeting of the South Shields Guardians a letter was read from the British Medical Association asking the guardians to petition Parliament to initiate legislation for the compulsory reception and detention in special houses for curative purposes of diseased inebriates, but the guardians were indisposed to meddle in the matter as they felt it would be unwise for them to ask for legislation in advance of public opinion. The subject was not therefore further proceeded with.

Whitby

Mr Martin Simpson a well known Yorkshire geologist, died at Whitby a few days ago at the advanced age of ninety three. Mr Simpson was well known to medical visitors to Whitby, as he was for fifty years curator of its museum, indeed, he did much, if not to found, at least to develop the museum, together with the late Mr R Ripley, surgeon of that place. His published works had a distinct value of their own, including a "Monograph of Ammonites of the Yorkshire Liass," "The Fossils of the Yorkshire Liass," "A Guide to the Geology of the Yorkshire Coast," "Geology of the Whitby District" &c. Some of these works date as far back as 1843. It will be thus seen that Mr Simpson was a student of geology when it was a far less popular pursuit than it is at present.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Edinburgh Royal Infirmary Annual Report

THE statutory general meeting of the contributors to the Royal Infirmary was held on Monday, Lord Provost Russell presiding. The treasurer and clerk submitted the report by the managers for the year to Oct 1st last. The number of patients remaining in the hospital at Oct 1st, 1891, was 610, the number admitted from that date to Oct 1st 1892, was 8027, the total number treated being 8637. Of these there were dismissed cured, 3769, relieved, 2818, on other grounds, 884, and died in the hospital, 605, while the number remaining was 561. Of the cases brought to a termination 3844 were medical and 4232 surgical. The daily average number of children in the wards was 58, most of whom were treated in the surgical wards. The average daily number in the hospital was 652, the greatest number being 691 and the lowest 575. The average time each patient was under treatment was 26.6 days. In the preceding year the total number of patients treated was 8769 and the average daily number in the hospital was 648, and the average time each patient was under treatment was 26.9 days. Of the cases 3607 were from Edinburgh, 544 from Leith and 3925 from the country. The percentage of deaths to the whole of the medical and surgical cases was 7.0 but, deducting 134 which occurred within forty eight hours after admission the percentage was reduced to 5.4. The number of patients admitted to the Convalescent House was only 621, owing

to the closing of the house from June for extension. In addition to the number of inpatients given above there were about 23,000 patients treated in the out-patient departments, which include special departments. The ordinary income was £30,630 10s 3d, as compared with £31,167 13s 11d in the previous year. The income includes donations and legacies under £100. The managers point out with satisfaction that the sum subscribed by the country districts has increased, but that the church collections in the city are still below what they were. The ordinary expenditure has been £41,969 19s 5d, as against £40,400 10s 9d for the preceding year. This increase is due to the greater cost of articles of maintenance, an increase in wages and a larger expenditure on furnishing and repairs. During the year a sum of £11,699 12s 6d was expended on the erection of the new home for nurses, two new lecture theatres and other necessary additions. There was also spent on the purchase of property for the extension of the infirmary the sum of £17,997 5s 1d. Owing to these various causes the debt now due to the bank is £36,979 8s 9d and in view of this the managers make an appeal for large benefactions. Reference is then made to the nursing staff, and it appears that during the year 593 applications were received for admission to the training school, while several requests to train pupils for other institutions had to be refused. The most important points in the history of the infirmary during the year are the completion and occupation of the new home for nurses. This allows of an increase in the number of nurses, which was necessary. The dispensing department is also to be enlarged. A detailed account is given of the negotiations in connexion with the application by the Scottish Association for the Medical Education of Women for their students to be admitted to the infirmary for clinical instruction. Owing to the acquisition of property in Lauriston lane two wards were set free, and these, furnished with twenty beds each, were made available for the instruction of women without encroaching on the wards hitherto used by male students. Arrangements have further been made whereby women students may receive clinical instruction in one of the general medical wards and in the special departments, so that in all 162 beds have been placed at their disposal. In addition they are allowed to attend the out patient department and the pathological theatre at certain times. The report then deals with the negotiations regarding the purchase of the site of the old Sick Children's Hospital, which were successfully carried out, and it is hoped money will be forthcoming for building on the ground thus acquired. The Convalescent House when completed will have accommodation for 100 patients.

The Health of Edinburgh

For the last week of the year the deaths numbered 118, making the rate of mortality 23 per 1000. Of the total deaths 19 were due to brain diseases, 56 to chest diseases, 12 to debility and age and 17 to zymotic diseases, of which 2 were due to diphtheria, 13 to measles and 2 to whooping cough. The intimations for the week were Typhoid fever, 3, diphtheria, 4, small pox, 1, scarlet fever, 43, and measles, 316. For the year the number of deaths was 4746, making the death rate 17.92 per 1000. There were 1742 deaths under five years and 1170 above sixty, of which 199 were above eighty and 25 above ninety years. Diseases of the chest caused 1607 deaths and zymotic diseases 641, of which 3 were due to typhus fever, 23 to typhoid fever, 42 to diphtheria, 69 to scarlet fever, 396 to measles, 82 to whooping cough, 20 to erysipelas and 1 to small pox. The intimations for the year were 10,124 and comprised 18 typhus fever, 238 typhoid fever, 203 diphtheria, 8 small pox, 1856 scarlet fever and 7801 measles.

Health of Leith

The mortality in Leith last week was at the rate of 34.91 per 1000. There were 2 deaths from scarlet fever and 14 from measles.

The Christmas Vacation in Edinburgh

Classes resume to-morrow (Wednesday). There has been a good deal of grumbling, as there always is over the shortness of the holiday, it is only of a fortnight's duration.

The City Hospital, Edinburgh

The number of cases treated in this hospital during the year was 2144 and comprised Typhus fever 16 typhoid fever 132, diphtheria 75, small pox 8, scarlet fever 932, measles 493, whooping cough 54, erysipelas 172, influenza 39 and 223 were admitted for observation or placed in quarantine. The deaths numbered 124 or 5.78 per cent January 3rd.

and those who will contrast my article with Mr Moulin's account of his instrument will form their own opinions as to the "borrowing of ideas" and "misapprehensions." I should be most pleased to submit my urethrometer to you or any other judge. It is now skilfully perfected by the Messrs Arnold. For my part I did not wish Mr Moulin to assume the seraphic abnegation which he now displays in disclaiming all originality!—I am, Sirs, your obedient servant,
Crouch End, Dec. 31st 1892. JAMES MACMURDO

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Refuse Disposal Difficulty

THE Corporation have received a somewhat unexpected rebuff at the hands of the Local Government Board, who have refused to sanction a loan of some £60,000 for the purchase of Rampton Manor in Nottinghamshire, an estate which they had agreed subject to the Board's consent, to purchase and use for the disposal of such portion of the nightsoil of Manchester as cannot be utilised at Carrington, the Corporation's present sewage farm in Cheshire. As I mentioned in a previous communication, a long and careful inquiry was held several weeks ago, both at Rampton and here, by Mr Smith, one of the engineering inspectors of the Board and a great deal of evidence was tendered both for and against the proposal of the Corporation. The grounds on which the Board have refused their sanction appear to be, first, the distance over which the refuse would have to be carried by rail, and secondly, the strong opposition which the rural sanitary authority of Nottinghamshire has raised against the scheme. The result, however, of the Board's action in this matter will be to considerably hamper our city council in their attempts to dispose of the night soil and excremental refuse of the city. According to the evidence at the inquiry Rampton is most favourably situated and is well adapted for the purposes to which the Corporation desire to apply it, the place is very sparsely populated and the land appears to be greatly in need of manure. In fact, a considerable number of the farmers in the district have signed a memorial requesting that Manchester should be permitted to send manure to Rampton, and expressing the opinion that the land would be much improved by the process. It will be interesting to note how the Corporation will meet the present emergency. The city is fast increasing in size and will probably absorb many of the outlying districts as time goes on. No one has as yet proposed that the highly offensive contents of our middens and pails should be burnt within the city, and yet it is difficult to see how otherwise it is to be disposed of, unless some means can be devised of obtaining land to which the excremental refuse of the city may be applied.

Public Lavatories

For many years past complaints have been common as to the serious inconveniences to which visitors to Manchester (especially ladies) have been subjected because of the almost complete want of public lavatories within the city. This want is now in a fair way of being supplied. About two years since a pair of lavatories were fitted up in Albert-square to replace the hideous structure which previously did duty for a lavatory, and which was unanimously voted a great eyesore to a part of the city having some pretensions to architectural beauty. The present lavatories are two in number—one for each sex. They are built underground, after the fashion of those at the bottom of Regent-street, London. The lavatories are fairly well lighted, they are fitted with all necessary appointments and are free from objectionable smell. They are the property of the Corporation and are kept scrupulously clean by persons appointed for that purpose. A small charge is made for the use of the lavatory and water closets, as is the case in London. The public look upon them as a great boon, and the Corporation are so well satisfied with their experiment in Albert-square that they are now engaged in the construction of another similar pair under the pavement opposite the Royal Infirmary in Piccadilly.

Continued Spread of Small pox

Small pox still continues to spread in Manchester in spite of the efforts which have hitherto been made to stamp it out. In the first week of December twelve cases of the disease

were notified, in the second week fourteen cases, in the third nineteen and last week twenty cases. With one exception every one of the patients has been removed to the Monsall Hospital, which is accordingly becoming crowded. At the present time there are reported to be sixty seven cases of small pox at Monsall, and as all these cases have been sent in within the last few weeks there is no immediate probability that many of them will be discharged. The disease seems to be present in all the principal districts of the city, and recently it has shown a tendency to spread in the direction of Chorlton, which district was comparatively free from infection during the first few weeks of the epidemic. The medical officer of health has issued circulars to the millowners, proprietors of business establishments, occupiers of factories and workshops, and indeed to employers of labour generally, asking their co-operation in inducing their *employés* to submit to the operation of revaccination. He has also circulated a leaflet giving in plain language a short description of small pox so as to assist in its detection and thus to secure the calling in of medical aid and the early and prompt removal of infected persons to hospital. Attention is also directed in the leaflet to the provisions of the law against exposure of infected persons and things and against the conveyance of small pox patients in cabs, trams, railway trunks and other public conveyances.

January 3rd.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Christmas and New Year Tragedies

THE Assizes were only completed on Christmas Eve and it is lamentable to have to record two deaths from homicidal violence, one on Christmas Day, the other on New Year's Day. In the first case the victim was a woman and her husband has been committed for trial on a charge of wilful murder. In the second case the victim is a young man and at the inquest held to day the jury returned a verdict of wilful murder against a young woman who was seen to stab him.

Execution at H M Prison, Walton

Cross Duckworth, who was tried at the recent Assizes for the wilful murder of a little girl aged nine, was executed on the 3rd inst at Her Majesty's Prison, Walton. The deceased was found dead with a handkerchief stuffed in her mouth, and this had been done with such violence as to tear the soft palate from its attachments. The prisoner was found guilty by a complete chain of circumstantial evidence, and though the jury recommended him to mercy the surroundings of the case were such as fully to justify the Home Secretary declining to interfere with the sentence of death. It is to be hoped that the prisoner's fate will act as a warning and deter other men from committing or even attempting a crime which has been terribly frequent of late—the violation of young females.

Jan. 4th, 1893

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Durham

MR F PAWSON, a noted football player, died at the County Hospital at Durham this week. Mr Pawson unfortunately met with an accident during play by colliding with another player, in consequence of which he was removed to the hospital on Oct. 1st last. His spine was injured and paralysis ensued, so that only the faintest hopes were entertained from the first of his recovery.

Small-pox in the North

From the prevalence of cases of small pox up and down the county our sanitary authorities are on the alert, and hospital questions and vaccination are now prominent. Cases are reported at Newcastle and Durham city and county. As a rule they are introduced and propagated by tramps and vagrants as before noticed, but so far nothing like an epidemic form of the disease has been noticed in the north. A case of small pox having been found in the casual wards of the Sunderland workhouse, and the day afterwards another case being observed, the guardians promptly met and decided

The population of France in 1891 was 38,343,192. The collation of the marriage rate since 1884 is interesting

1884	289 555 marriages
1885	283,170 "
1886	283,208 "
1887	277,060 "
1888	276,848 "
1889	272,934 "
1890	269 332 "
1891	285,458 "

The fluctuations in the divorce figures since 1884 when M. Naget reintroduced that institution, are as follows

1884	66 per 100,000 households
1885	57 " "
1886	40 " "
1887	50 " "
1888	60 " "
1889	61 " "
1890	73 " "
1891	77 " "

Of the 656,347 children born in 1891, 443,227 were boys and 213,120 girls while 792,441 were legitimate and 73,936 illegitimate, these latter constituting 8.5 per cent. of the entire births. Of the 876,832 deaths 453,085 were male and 423,797 female. As in 1890, the death rate for 1891 was high the parts of France which were most tried in this respect having been the south-east and the west. In fifty-three departments the excess of deaths over births has entailed a total loss of 62,533, an inverse process having given to the remainder (24) a gain of 52,028. For the whole of the country there were for 1000 deaths 939 births. Of the 13,958 foreigners who married during 1891, 347 were of English nationality. The births comprised 26,475 foreigners, including 363 English. The death list included 17,626 foreigners 478 of them being British.

January 4th.

BERLIN

(FROM OUR OWN CORRESPONDENT)

Cholera in Hamburg

So far as I can judge from the reports in the newspapers the number of cholera cases in Hamburg last week was seven, the number of deaths from cholera two.

Pathologico-Anatomical Plates

Professor Kast (now in Breslau, formerly head of the Hamburg Infirmary) and Dr Theodor Rumpel have published pathologico-anatomical plates taken from fresh preparations with explanatory text. They have been assisted by an artist named Gummelt. The plates are very cheap, and are said to be excellent.

Medicine in the Middle Ages

Dr Julius Pagel private lecturer on the history of medicine in Berlin University has induced Dr Otto Paderstein to edit a part of the *Revocatum Memoriz* of Johannes de Sancto Amando a Belgian physician of repute who flourished in the thirteenth century. It is a manual of pathology and therapeutics which was much used by medical students six centuries ago and affords a valuable insight into the state of the science and art of medicine at that time. Dr Paderstein's edition, which is the first, is based on four manuscripts.

A Practitioner Sentenced for Fraud

A Leipzig practitioner, Dr von Tischendorf a man of good reputation, with an income of about £500 a year, was sentenced to eight months imprisonment on Christmas Eve for fraud. He had a private dispensary and received from each patient belonging to the sick fund of the place only 1 mark and 25 pfennigs (1s 3d) a day for board, lodging and medical attendance. In order to eke out this miserable pittance, he reckoned more than the actual number of days in his accounts. In ten accounts which were laid before the court thirty-two of the ninety-nine entries were proved to be false. The court took the good reputation of the accused and the inadequacy of his pay as doctor to the sick fund into account as extenuating circumstances.

Miscellaneous Items

Owing to the death of Professor Wilhelm Braune, Dr Fick of Würzburg has been invited to teach anatomy in

Leipzig University, with the title of Extraordinary Professor. Professor Werner Spalteholz has been appointed curator of the anatomical museum there.—Wilhelm Marmé, Professor of Pharmacology at Göttingen, has received the title of Privy Medical Counsellor.—The "Society for the Investigation of Nature" is celebrating the hundred and fiftieth anniversary of its foundation to-day at Dantzig. A history of the Society has been prepared for the occasion.—A committee has been formed for the purpose of commemorating, by the erection of a bust, the twenty years services of Surgeon General Mehlhausen as medical director of the *Charité*.—The medical faculty of Berlin University has forwarded to M. Pasteur a letter of congratulation in Latin on the occasion of his seventieth birthday.

Berlin, Jan. 2nd.

NEW ZEALAND

(FROM OUR OWN CORRESPONDENT)

The Sanitary Condition of Wellington

A LETTER appeared in THE LANCET of Sept. 24th last signed by Dr Chapple of Wellington, in which that gentleman refers to my article on the above heading as "painfully unjust, as my report most clearly proved." Unfortunately Dr Chapple does not give his reasons for characterising my remarks in this manner, nor, indeed, do I think it possible for him to do so since the article in question is in the main a *resume* of his own sanitary report. If any "scathing criticism" makes its appearance it has emanated from Dr Chapple himself. When the report on the sanitary condition of the city first appeared the universal opinion expressed was that at last a man had been found who struck out straight from the shoulder in such a manner as to show very clearly the absolute necessity for immediate sanitary reform. Dr Chapple's report, I maintain once more, most clearly demonstrated that the condition of the city at the time of writing was such as reflected disgrace on the authorities. It has astonished me not a little, too, to find Dr Chapple making the assertion that "previously to 1890 there was comparatively little typhoid fever existing." I reiterate once more that dirt, disease and death have given this city an unenviable notoriety among the cities of the colony for years past. If Dr Chapple will look up the Registrar General's reports for, say, the past ten years he will find that typhoid fever has claimed many victims yearly (I have recently forwarded you the statistics) and that the death-rate from this disease was on the increase at the moment that his report appeared. As a matter of fact, Wellington has been the 'home' of typhoid fever in this colony for at any rate, the past fifteen years. Numerous instances could, if necessary, be cited where cases of typhoid fever occurring in other parts of New Zealand have been actually traced to a Wellington infection. Another point I wish to refer to in the letter and I have done. Dr Chapple accuses me of attacking the sanitation of the whole city. In this respect, too his letter is not correct. He has evidently not read my article with any care or he would have come upon the following sentence:—
"The yearly outbreaks of fever have been confined to a small area in the Te Aro end of the city." As a matter of fact an acknowledged area of about 100 acres teeming with faecal accumulation (according to the recent report) in the centre of a city cannot conduce to a 'comparative immunity from all forms of zymotic disease.' In conclusion I heartily congratulate the ratepayers of Wellington on their recent determination to purify the city from all infectious diseases and no one wishes them more thorough success than your own correspondent.

Nov 29th, 1892.

BOMBAY UNIVERSITY AND THE M.B. DEGREE.

Another effort is being made by the Senate of the Bombay University to put their medical degrees on a new basis. With this object in view it has been proposed to change the degree of L.M. and S. to M.B. the Arts examination being substituted for that of Matriculation. Another suggestion is that the 'intermediate' in Arts or the final B.Sc. be the preliminary test, and that the L.M. and S. degree remain until an equivalent diploma is granted by some licensing body. Other suggestions have been made and there is a general feeling that some change is necessary. At present the discussion on the matter by the Senate stands adjourned.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Small-pox Prosecution for Exposure

ON Saturday last, in the South Police Court, a man was prosecuted under the 142nd Section of the Public Health Act for having exposed himself in a public vehicle while suffering from small pox. The prosecution was instituted by the Corporation on the recommendation of the Local Government Board. From the evidence given it appeared that the defendant contracted the disease in Liverpool and came to Blackrock, near Dublin, on Nov 18th, 1892, where he was seen by the dispensary medical officer, who recommended him to go to Loughlinstown Union, but he refused and said he would go to Dublin. He was duly warned to take all necessary precautions, but nevertheless travelled from Blackrock by an ordinary train to Dublin. He walked through the streets of Dublin and on Nov 24th was admitted into Cork street Fever Hospital. The defendant said that he did not at the time think he was suffering from the disease, he did not feel unwell and he thought he had merely a rash of some kind. The magistrate pointed out the danger of travelling while affected with a disease of the kind and inflicted a fine of £3, which subsequently was reduced to £2, as the defendant's clothes had all been burned.

The Belfast Hospital for Sick Children

Two vacancies have occurred in the staff of this hospital by the retirement of Mr John Fagan, who was one of its two original founders and has been surgeon at this institution since 1873, and by the resignation of Dr Campbell, who for the past two years has been assistant surgeon. A number of candidates are in the field for the two appointments, the posts being highly valued as affording exceptional opportunities for studying the diseases of infancy and childhood.

Medical School Dinner

I understand that arrangements are now being completed for having a dinner in connexion with the Belfast School of Medicine on Thursday, Jan 26th. It is expected that all the teachers and a large number of the old pupils will be present.

The Union Infirmary

At the usual weekly meeting of the Belfast Board of Guardians held on Jan. 3rd it was decided to grant Dr Seaton Reid a retiring allowance of £100 and Dr Bryce Smith £50 per annum. In reference to the admission of students, a resolution was carried requesting the Local Government Board to give effect to the resolutions adopted on Dec 13th admitting medical students to clinical lectures.

Progress of Belfast

During the past year (1892) although for a lengthened period there was a strike in the building trade, 2112 new buildings were erected and there has been an increase in valuation of £24,013. During the past thirty-one years there were 41,371 new buildings erected in Belfast and in the same time an increase in valuation is noted of £461,428. Belfast is still growing with leaps and bounds, and in no city in the United Kingdom is work more plentiful.

January 4th

PARIS.

(FROM OUR OWN CORRESPONDENT.)

French Bacteriologists in New South Wales

SOME years ago Madame Pommery, whose name is so familiar to epicures, began to utilise some waste land over her champagne cellars for the breeding of rabbits destined to serve as food for the powder expended by her guests during the shooting season. Madame Pommery was evidently unacquainted with the rabbit scourge that has proved so detrimental to agricultural operations in Australia or she would never have made such a hazardous experiment. Finding that the rodents above ground were fast becoming more numerous than the bottles in the cellars beneath and that their burrowing threatened the stability of the said cellars, she consulted M Pasteur. That magician, by sowing chicken-cholera

broadcast amongst the obnoxious animals, succeeded in killing them all in a fortnight. Fortified by this brilliant result M Pasteur, it will be remembered, despatched to Australia a commission headed by his relative, M Loir, with the object of repeating the massacre on a large scale in our progressive but rabbit-ridden colony. It appears, however, that the Colonial Government had hitherto been paying so much a head for every rabbit killed and certain individuals who gained their livelihood in this way naturally objected to the putting into practice of the more expeditious Pasteurian method. The wire netting industry was also well to the fore in the outcry raised against the Gallic Commission and the bugbear, chicken cholera, was advanced in order to frighten poultry breeders. The Government was powerless against this artfully contrived agitation and the justly offended *arants* had to content themselves with a sop—viz., the founding by the authority of a Pasteur Institute at Sydney wherein they could, on the condition that they left the playful “bunny” strictly alone, undertake bacteriological researches that might benefit the colony in other but unrodent directions. That the labours of this enlightened band of scientists have not been unfruitful since their installation at the Sydney Institute is apparent from a report issued by the director, M Loir, which appears in the November number of the *Archives de Medecine Experimentale*. The subjects studied were *charbon* (anthrax) and the pleuro pneumonia of cattle. Subcutaneous inoculation of charbon virus proved fatal to the kangaroo rat, the Australian cat (a carnivorous marsupial), the kangaroo and the Australian bear (kaola). Introduced into the system through the stomach the virus killed the kangaroo rat, but failed to do so in the case of the Australian cat, appearing to have, on the contrary, conferred on that animal immunity against subsequent inoculations. Enormous sums are lost annually in Australia through the ravages of bovine pleuro-pneumonia. The insufficiency of railway communication explains the spread of the disease amongst cattle, most of the roads being probably infected to a large extent. A method of inoculation against this disease is known and extensively practised. This consists in inoculating the active virus into the animal's tail. Local oedema is produced and sometimes gangrene, but ordinarily the beast recovers and acquires immunity against the dread disease. Unfortunately, the virus keeps badly, and inoculations are only practised when an epidemic breaks out in a herd. By this time the disease has spread and inoculation comes too late. M. Loir and Germont were requested by the Queensland Government to prepare on a large scale cultures of the virus which could be supplied to cattle raisers. This they have succeeded in doing by a proceeding due to M Pasteur. The virus is inoculated into the shoulder or the dewlap of the calf. Considerable oedema ensues and puncture of the sac gives issue to as much as two litres of serum. M Loir has discovered that in order to collect the liquid at the acme of its virulence it must be taken when the calf has a temperature of 41° or 42° C. He has also proved that the liquid is as active as the natural virus taken from the lung of an animal affected with idiopathic pleuro pneumonia. There is unfortunately a limit to the time during which the lymph can be kept, the activity, when preserved in sterilised tubes, disappearing in twenty days. Attempts to isolate the microbe of this disease have hitherto failed. The above discovery is nevertheless a most important one, the immunity conferred by the inoculation having proved very perfect. The following experiment confirms this statement. 2000 cattle are inoculated with the virus derived by the above described (Pasteur's) method from a calf. The herd is despatched on a journey of 2000 kilometres, the addition being made to their number at the start of 19 un inoculated animals. The journey accomplished, it was found that not one of the inoculated beasts had contracted pleuro pneumonia, whereas of the 19 unprotected ones 8 had succumbed to it.

Statistics relating to the Population of France for 1891

The report of M Lax, director of the Office du Travail, has just been sent to the Minister of Commerce. From this report it appears that there were registered during 1891 in the whole of France 285,458 marriages, 5752 divorces, 866,377 births and 876,882 deaths. Compared with the figures of 1890 I find an increase of 18 126 marriages, 295 divorces, 28,318 births and 377 deaths—that is to say, while the number of deaths has remained virtually constant, the marriages have increased 6 per cent. and the births 3.37 per cent. It will be noticed that the deaths exceeded the births by 10,505. The general rate of mortality was 22.6 per 1000.

INSPECTOR GENERAL OF HOSPITALS JOHN ROBERT TAYLOR, C.B., F.R.C.S

THE death of this officer at Cheltenham on Dec. 23rd last at the age of eighty three calls for more than a passing notice at our hands, for the late Inspector General Taylor had in his time a long and very distinguished career in the Army Medical Service. He retired in 1863, and this, together with his death at an advanced age, would naturally tend to weaken the recollection of services performed so long ago, and yet there are few men who can show such a record of good and active service as the late Inspector General Taylor possessed. He was the son of an army surgeon who died in the service at Gibraltar in 1812. He commenced his military career in the reign of William IV as assistant-surgeon, 58th Regiment. In 1838 he went to Canada, where he had charge of the wounded after the fight at Point-au Pelée. Up to 1839 he served at Chambly with the 1st Dragoon Guards and the 15th Regiment engaged in the Canadian Rebellion. In 1842 he joined the 29th Regiment in India as surgeon, and he served with it in the Sutlej campaign, 1845-46, including the actions of Ferozeshah and Sobraon, where the losses of the regiment were extremely heavy, being nearly one in four of the officers and men engaged. In 1848 he exchanged into the 80th Regiment, and served with it in the campaign in Burmah, including the affairs of Martaban, Rangoon, and the captures of the Great Dagon Pagoda and of Prome. In 1854 he was gazetted first-class staff surgeon and appointed principal medical officer at Chatham. In March 1855, he was ordered to the Crimea where he joined the third division of the army under Lord Raglan. He was present with his division in the assault of June 18th and in the taking of Sebastopol on Sept. 8th. He was gazetted deputy inspector general in 1855. It was in this war that he introduced his scheme of systematic classification and tabulation of gunshot wounds occurring in the field, which he had initiated in the Sutlej Campaign and completed during the Crimean War, in a form since adopted in all army returns. In 1856 he was made a Companion of the Bath, in 1858 he was gazetted inspector general, and on his return to England he was, in 1859, appointed one of Her Majesty's honorary surgeons. He was principal medical officer at Fort Pitt, Chatham, until 1861, when he proceeded in the same capacity to the Cape, being also commissioned to inquire and report upon a scheme which the Government had in view for establishing a sanatorium there. His report was adverse to the scheme. In 1862 he returned to England and was appointed principal medical officer at Aldershot, where he remained until his retirement in 1863. He was awarded a good service pension from the grant for distinguished and meritorious services.

SURGEON COLONEL C H Y GODWIN

THIS officer—the telegraphic news of whose death we briefly recorded last week—entered the Army Medical Service as an assistant-surgeon in October, 1860, became surgeon in March 1873, surgeon major in May, 1875, brigade-surgeon lieutenant colonel in October, 1886, and surgeon colonel in March, 1892. At the time of his death, which took place at Rawal Pindi on Dec. 23rd last, at the age of fifty four, he was the principal medical officer of the Rawal Pindi Division. The deceased officer after serving for a long time in India, became surgeon to the Royal Arsenal, Woolwich, and went on active service to Egypt, where he did excellent work in organising and managing the hospital at Suez and in treating the sick and wounded sent there. Although specially selected for that post on account of his surgical skill and knowledge, his service there was not a remunerative one and he more over, suffered greatly in health from the effects of fever and climatic disease. He subsequently went to Netley as Assistant-Professor of Military Surgery, and on the retirement of Sir Thomas Longmore, C.B., he was appointed his successor, but resigned the professorship in consequence of the financial loss which the holding of it entailed and went to India where he had only arrived a few months before he died of dysentery, leaving a widow and children to mourn their loss. The Army Medical School at Netley is the institution through which all officers of the British and Indian Medical Services have to pass, and the best men are supposed to be selected to fill the posts in its teaching staff. It seems therefore, neither just nor expedient that medical officers specially selected for these appointments should not be well paid and that the

emoluments attaching to them should not be sufficient to tempt the best men to seek for them and to try, by the character of their work, to retain them, and yet such does not appear to have been the case in the present instance, for Surgeon Colonel Godwin, as we have seen, retired from the professorship of Military Surgery soon after his appointment thereto. The late officer was an excellent surgeon and quite *au courant* with the most recent scientific advances in surgery. He edited the latest edition of Porter's well known handbook, and by his revisions and additions to that work did all that was possible to maintain its character as an excellent practical handbook for the military surgeon. He was always ready to take part in any surgical work or scientific investigation, and his loss will be greatly felt in the service to which he belonged and of which he was so worthy a member.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent B.S. (Honours) Examination—

First Class.—Edward Percy Paton, M.D. (Scholarship and Gold Medal), St. Bartholomew's Hospital; Hamilton A. Ballance (Gold Medal), University College; Henry Stephen Sandifer, King's College; Chas. Satchell Pantin, E. Thos. E. Hamilton, B.Sc., and Tom Robinson Taylor, B.Sc., Guy's Hospital.
Second Class.—John Lacy Firth, M.D., University College; Leonard Rogers, St. Mary's Hospital; Wm. Black Jones, St. Bartholomew's Hospital; Chas. Henry Preston, Owens College; Manchester Royal Infirmary and London Hospital; Thomas David Lister, Guy's Hospital.
Third Class.—Francis Jordan Coleman, Alfred Wm. Sheen and John Wm. Frank Jewell, Guy's Hospital; Charles Edwin Wheeler, St. Bartholomew's Hospital.

* Worthy of Medal.

FOOTBALL CASUALTIES.—A young man, whilst playing last week in a match on the Goddard street Ground, Crewe, fractured his clavicle. During a match in the same week, at Glossop, between North End and Stocksbridge, a member of the latter team sustained a compound fracture of the leg and was admitted to Wood's Hospital. A young man of Jarrow, who was injured in the spine while playing in October last in a match between Durham City and Westoe and was removed to the Durham County Hospital, died there on the 2nd inst. The injury received brought on paralysis.

THE SOCIETY OF PUBLIC ANALYSTS.—On Wednesday the annual dinner of this society was held at the Criterion Restaurant, Sir Charles Cameron, M.D., being in the chair. The company included a large number of gentlemen engaged in analytical science. The President, in proposing "Success to the Society of Public Analysts," remarked that the past president, in vacating his seat, was leaving the Society in a greatly increased state of efficiency. Mr. Otto Hehner, in responding to the toast, testified to the improved condition of analytical science, to the value of the work achieved by the Society and to the necessity of enhanced vigilance on the part of those engaged in counteracting the designs of fraudulent dealers in food and drugs.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Fishmongers' Livery Company and the Salters' Livery Company have granted twenty five guineas and ten guineas to the Royal Westminster Ophthalmic Hospital respectively.—The secretary of the Children's Hospital Sunday School Fund, Birmingham, has handed over £281 17s. 10d. to the committee of the Children's Hospital, Birmingham, being the proceeds of the thirteenth annual collections made in the various Sunday schools of that city and neighbourhood.—The treasurer of the Queen's Hospital, Birmingham, has received £75 from the Birmingham Charity Sports 1892.—The ball in aid of the St. John's Convalescent Home for Children, Brighton, which took place on Nov. 30th last, resulted in the sum of £109 17s. being handed over to that charity.—The executor of the late Mrs. E. Hohn has forwarded a cheque for £100 to the Hospital for Epilepsy, Regent's park.—The late Mr. Thomas Wm. Christie, M.R.C.S., Liverpool bequeathed £100 to the Castlebar Infirmary, Mayo.—Mr. Wm. Robert Barker, late of New Bond street, London bequeathed £100 to the Cheltenham Hospital.—Mr. Laurence Morrissey has left £200 each to Jervis street, Mater Misericordiae and St. Vincent's Hospitals and £100 to the Hospital for Incurables, Dublin.

Obituary.

THOMAS HAWKSLEY, M D LOND, M R C P LOND

IN taking a retrospect of the career of those members of our profession who have attained to success and eminence in their respective spheres of action it will be found that in some instances certain favourable advantages have existed in connexion with the individual, such as blood relationship, with one who has held an exalted and influential position in the profession, or with someone who is prominent in the social scale and is able to materially advance the career of the aspirant to fame, and when these advantages have existed and their possessor is gifted with sound knowledge, energy, judgment and good health success comes rapidly. There are others, however, who have not been favoured by any of the advantages which so much assist a man in his professional career and yet owing to their own energy and perseverance have met with great success and led most useful lives. To this category the late Dr Hawksley belonged, and, moreover, he laboured under the disadvantage of feeble health, and in consequence of disease in one of his lower limbs was rendered lame for the greater portion of his life, but his physical weakness was compensated for in a great measure by marked mental activity and determination of character. Born in 1820, Dr Hawksley at the finish of his general education determined to follow the profession of medicine, and prior to entering upon the usual curriculum at one of the public schools he acted as assistant to Mr Fincham of Spring-gardens, a practitioner of the old school, who attended a considerable number of people of all classes in the neighbourhood and in Westminster. Here Dr Hawksley had a good opportunity of seeing the drudgery incidental to the duties of the general practitioner fifty years ago and was a careful witness of the routine treatment which was carried on in those days even by highly educated men, for at that time the use of the lancet was much in vogue and inflammatory disorders, such as pneumonia and peritonitis, were treated by the most violent remedies, such agents as mercury and antimony being used in frequent and excessive doses. In fact, in those days symptoms only were combated and little heed was given to the causes which produced the morbid phenomena in question. During this time Dr Hawksley paid much attention to the study of *materna medica*, always a favourite subject with him. Among other good advice which he gave to a junior pupil just entered upon professional study, he recommended him to write out the whole of Phillips' Pharmacopoeia, which was at that time the standard work. He entered at the school of King's College in 1840, residing in the house of a practitioner in the neighbourhood. This was at a period when a student could qualify himself in about two, or at least three years and Dr Hawksley was not long in doing this. He made the best use of the opportunities afforded him by the distinguished teachers who were then raising the reputation of the school and was noted for his energy and intelligence, gaining a high position amongst his fellow pupils, and in a very short time obtaining his qualification. He married and took a small house in Margaret-street, Cavendish square, and there commenced the practice of his profession. After residing there for some years he took the degrees of M B and M D of the London University, and in 1854 obtained the Membership of the College of Physicians. His favourite study being in that direction, he attached himself as physician to the Infirmary for Diseases of the Chest in Margaret-street. He subsequently removed to George-street, Hanover square, where he resided for several years, but later changed his abode to Brook street. At this period of his life he was not only engaged in an extensive practice, but was devoting himself to sanitary science and matters of philanthropy, he took a leading part in the establishment of charitable societies and employed his pen on the subjects of pauperism, the charities of London, the culture of the children of the people and the sewerage of London. Besides these, he wrote papers on various medical subjects and warmly advocated the use of the earth closet. For some time he resided at Brighton coming up to town frequently to attend his patients, and ultimately he purchased some property at Chertsey before withdrawing from the practice of his profession. At this latter place he developed a scheme which he had long revolved in his mind

on the property he purchased he erected a building which was formed into a School of Handicraft for Destitute Boys, who were rigorously trained to useful mechanical arts and were thus saved from poverty and crime and sent out into the world as redeemed and useful members of society. In this noble work Dr Hawksley spent the energies of his philanthropic mind during the last few years and was enabled to see it crowned with success. It is computed that he devoted as much as £30,000 to this object alone.

Always more or less feeble in frame, Dr Hawksley had during the latter years of his life suffered much in various ways. Some ten years since he underwent two operations for stone in the bladder and subsequently during his life had much vesical trouble, but to the astonishment of those who had known him long he reached the age of upwards of seventy and was cut off by an attack of obstruction of the bowels, for which colotomy was performed. Dr Hawksley's success was due entirely to his own perseverance. Without any brilliant qualities, he was a conscientious and diligent cultivator of his profession, he was a shrewd observer, and not only did he take a deal of trouble in investigating the diseases of those he attended, but he had the fortunate gift of impressing his patients with the fact and consequently he gained their entire confidence. It is not often that men in our profession have such opportunities of practically showing the results of that philanthropic spirit which animated the subject of this memoir. His useful life will prove a great example to those who may be placed in similar positions of being able to benefit their fellow creatures.

JAMES R D P BRIGHT, M D, M R C P

THE subject of the present notice, who died on Dec 18th at the very advanced age of eighty eight years, was some forty years ago a well known and a much respected physician at the West end of London, having successfully carried on a practice at Cambridge square for a period of about twenty years. Dr Bright was the youngest son of Captain Bright, R M L I, and was born at Stonehouse, Devonshire, on March 4th, 1804. When about six years old the Woolwich division of Marines was formed, and Captain Bright being appointed barrack master, the family removed to Woolwich. Dr Bright, with his two brothers, was educated at Blundell's School, Tiverton, which in those early days had so high a reputation that their father considered the advantages obtained outweighed the difficulty presented in accomplishing so considerable a distance in the then coaching days, and many a good story could he relate of the adventures of his early schoolboy days, when he was contemporary with the celebrated "Jack Russell" and many other Devonshire worthies. On leaving school, having a desire to enter the medical profession, he was placed with Mr Bannett of Fulham, who was at that time in an extensive practice. After completing his curriculum at Guy's and St Thomas's Hospitals in the days of their amalgamation and obtaining the M R C S and L S A. qualifications, he was for a short period in the United East India Company's service and took three voyages to Calcutta, the last in the *Cesar*, when he was in medical charge of a large number of troops. After his return from this voyage he settled in active practice in Brighton, where he was in partnership with the late Mr Philpott, brother to the then Bishop of Worcester. In the year 1834 Dr Bright removed to Wimbledon where he had a very large practice and where he remained until 1844 when he settled in the West-end of London, having in the meantime taken the degree of M D Aberdeen in 1840. While in London Dr Bright was for some years hon secretary to the Medical Benevolent Fund and also hon physician to the Institution for Governesses in Harley street, many of whom found in him a most kind friend as well as a skilful medical adviser. Dr Bright was admitted M R C P in 1859, he was also a Fellow of the Royal Geographical and the Geological Societies, in whose proceedings he took much interest. He wrote a work "On the Heart and Lungs," which he dedicated to his old friend and patient, Lord Cottenham, then Lord Chancellor and which went through several editions. Dr Bright left London in 1863, when he retired from practice and settled in Cheltenham, where he remained till 1878, and in 1882 he removed to Plymouth, where he died, much mourned and respected, on Dec. 18th, 1892. Dr Bright married a daughter of the late Mr John Hatchard by whom he had ten children, six surviving, the second of whom, Mr J A Bright is a member of the medical profession.

CORPORATION OF NORWICH.—Medical Officer of Health. Salary £400 per annum.

DERBYSHIRE ROYAL INFIRMARY.—Resident Assistant House Surgeon, for six months. Salary £10. Apartments, board and washing provided.

EARLSWOOD ASYLUM FOR IDIOTS. Redhill, Surrey.—Qualified Practitioner. Salary £400 with furnished apartments in the building together with coal and gas.

EAST LONDON HOSPITAL FOR CHILDREN. Glamis-road, Shadwell E.—House Surgeon. Board and lodging provided.

GENERAL INFIRMARY AND DISPENSARY, DONCASTER.—In-door Dispenser and Assistant to House Surgeon. Board, lodging and washing provided.

GUEST HOSPITAL, DUDLEY.—Resident Medical Officer. Salary £100 per annum, with board, residence attendance and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON. House Physicians.

METROPOLITAN ASYLUM BOARD.—Medical Superintendent at the Darent Schools for Imbeciles, near Dartford, Kent. Salary £450 per annum, with furnished residence, coal, gas, milk, garden produce and washing. (Applications to the Clerk of the Board, Chief Offices, No. 10, Fenchurch Street, Strand, W.C.)

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, GREENWICH ROAD, S.E.—Senior Resident Medical Officer. Salary £60 per annum, with apartments, board and washing.

TAUNTON AND SOMERSET HOSPITAL, TAUNTON.—Assistant House Surgeon, for six months. Board, washing and lodging in the Hospital provided.

VICTORIA HOSPITAL FOR SICK CHILDREN, QUEEN'S ROAD, CHELSEA, S.W.—House Physician to the Inpatients. Honorarium of £50 per annum, and board and lodging provided in the hospital.

VICTORIA HOSPITAL FOR SICK CHILDREN, QUEEN'S ROAD, CHELSEA, S.W.—House Surgeon to the Inpatients. Honorarium of £50 per annum, and board and lodging provided in the hospital.

VICTORIA HOSPITAL, FOLKESTONE.—House Surgeon. Salary £50 the first year with an increase of £10 each year for the two following years, together with board and residence.

WEST HERTS INFIRMARY, HEMEL HEMPSTEAD.—House Surgeon and Dispenser who shall also be Assistant Secretary for two years. Salary £100 per annum, with board, furnished rooms, free light, attendance and washing.

WEST RIDING ASYLUM, WAKEFIELD.—Fourth Assistant Medical Officer. Salary £100 per annum, rising £10 annually to a maximum of £150 with furnished apartments, board, washing and attendance.

Medical Diary for the ensuing Week.

Monday, January 9.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., Fridays and Saturdays, at the same hour.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M. and on Tuesday, Wednesday, Friday and Saturday at the same hour.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations 2 P.M. Thursday 2.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M. and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations 2 P.M.

ROYAL ORTHOPEDIC HOSPITAL.—Operations 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M., Thursday 9 A.M. Eye Department, 2 P.M.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road).—5 P.M. Mr. Lencox Browne. Diseases of the Nares, Pharynx and Larynx.—Mr. Wyatt Wingrave. Demonstration of the Commoner Micro-organisms occurring in the Nose, Throat and Ear with their accompanying Tissue Changes (Lantern and Micro Slides). (Post-Graduate Course.)

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-sq. W.C.).—8 P.M. Annual General Meeting. Casual Communications.—Mr. Ackey. A peculiar case of Bone in Dentine.—Mr. D. Hepburn. Osses Union of Molar Teeth. Paper.—Dr. E. W. Roughton. Micro-organisms of the Mouth (with lantern demonstration). The President will deliver his Valedictory Address.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. J. S. Bristowe. Syphilitic Affections of the Nervous System. (First Lettsomian Lecture.)

Tuesday, January 10.

GUY'S HOSPITAL.—Operations 1.30 P.M. and on Friday at the same hour.

Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., Friday, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations 2 P.M., Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Skin Department, 1.45 Saturday 9.15.

ST. MARK'S HOSPITAL.—Operations, 1.30 P.M. Consultations Monday 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays 1.30 P.M. Electro-therapeutics, same day 2 P.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Dr. A. Haig. The effects of the Iodides on Arterial Tension and the Excretion of Urates.—Mr. D. Argy Power. Cases to illustrate the Relationship which exists between Wryneck and Congenital Hematoma of the Sternomastoid Muscle.

Wednesday, January 11.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M., Saturdays, 2 P.M. Obstetrical Operations, Thursdays 2 P.M.

CHARING CROSS HOSPITAL.—Operations, 8 P.M., and on Thursday and Friday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M. Saturday same hour.

LONDON HOSPITAL.—Operations 2 P.M., Thursday and Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M. Dental Department, 8.30 A.M. Eye Department 2 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M. and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

HUNTERIAN SOCIETY (London Institution).—8.30 P.M. Mr. H. W. Denton-Cardew. Electricity in Every-day Practice (with demonstration).

Thursday, January 12.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday 1.30 P.M. Ophthalmic Operations, Friday 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M. Ear and Throat Department, 9 A.M. Eye Department, 2 P.M.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—Dr. E. Clifford Beale. Two cases of Myxodema treated by Thyroid Extract.—Dr. G. O'Reilly. (1) Case of Lumbar Abscess opened when 70 oz. of pus were evacuated, cure. (2) Case of Perityphilitis with peritonitis, absorption cure.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road).—5 P.M. Dr. Dundas Grant. Diseases of the External Meatus (concluded).

Friday, January 13.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Eye Department, 2 P.M.

CLINICAL SOCIETY OF LONDON.—Dr. de Havilland Hall. A case of Rhinolith.—Sir Dyce Duckworth. A case of Inherited Gout with production of Tophi at an early age.—Mr. Davies Pryce (Introduced by the president). On Uratic Deposits in the Conjunctival Membrane.—Dr. Penrose and Dr. Lee Dickinson. Cases of Abscess beneath the Diaphragm in connection with Perforating Gastric Ulcer.

Saturday, January 14.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and Skin Department 9.15 A.M.

Births, Marriages and Deaths.

BIRTHS.

COVENTON.—On Jan. 1st, 1893, at Indore. Perensy road, St. Leonards-on-Sea, the wife of Chas. A. Coventon, L.R.C.P. Lond., M.R.C.S. Eng. of a daughter (Ruby Helen).

FAWSETT.—On Jan. 3rd, 1893, at High street, Lewes, Sussex, the wife of Frank Fawcett, M.B., B.S. Lond., of a daughter.

FENN.—On Dec. 30th, 1892, at Richmond, Surrey, the wife of Edward L. Fenn, M.D., M.R.C.P. of Grey Friars, Colchester, of a daughter.

SIEVEKING.—On Dec. 31st, 1892, at Gwydir House, Cambridge, the wife of Alfred Robert Sieveking of a daughter.

MARRIAGES.

HAUSEMAN-WARD.—On Wednesday Dec. 28th, 1892, at Holy Trinity Church, Twickenham, by the Rev. David Anderson, Rector of St. George's, Hanover square, assisted by the Rev. P. B. Drabble, Vicar of Holy Trinity, Twickenham, Dr. James Gilpin, Hausman of the Manor House, Houghton-le-Spring, Durham, to Jane Isabel, eldest daughter of Martindale Cowdale Ward, M.D. of Salisbury, Twickenham-common, and granddaughter of the late Matthew Jameson, of Thirsk, Yorkshire.

JOHNSON-KING.—On Dec. 20th, 1892, at St. Matthew's, Bayswater, by the Rev. W. E. Emmet, M.A., Vicar of St. Mark's, Notting Hill, Raymond Johnson, M.B., F.R.C.S. of 20 Weymouth street, Portland place, W., eldest son of Raymond G. Johnson of 48, Ladbroke-road, W., to Mary Helen, eldest daughter of Robert King of 15, Lansdowne-road W.

TOPPING-WHITLOCK.—On Dec. 29th, 1892, at Great Yeldham Church, John Phillip Topping, M.B. C.M. of Forest-gate, Essex, to Emily second daughter of Walter Whitlock, Esq. of Poole House, Great Yeldham, Essex.

DEATHS.

BARSTOW.—At 8, Hoxton street, Gillingham, Bradford, on Dec. 20th, 1892, Arthur Henry Barstow, L.R.C.P.S. Ed., L.F.P.S. Glasg., aged 29.

CRANE.—On Dec. 10th, 1892, at 'The Wilderness,' Port of Spain, Trinidad, Lillie the wife of S. Leonard Crane, C.M.G. M.D., aged 47.

JACKSON.—On Dec. 24th, 1892, at Scarborough Villa, Leamington, Peter Alfred Jackson, late Surgeon 3rd Battalion Leicestershire Regiment, aged 71.

M'DONVILL.—At Park House, Park Lane, Stoke Newington, M.D. Edin., M.R.C.S. Eng. in 3rd year.

STAINS.—On Dec. 29th, 1892, at the Royal Infirmary, Liverpool, in the 63rd year of her age, Miss Emmeline Stains for over eleven years Lady Superintendent of the Royal Infirmary and of the Liverpool Training School and Home for Nurses, after twenty five years of invaluable nursing work.

WALLACE.—On Dec. 2nd, 1892, at Hotel des Palmiers, Nice, Brigade-Surgeon John Wallace, late of Devonport.

WHITMARSH.—On Dec. 25th, 1892, at Medina terrace, Brighton, William Michael Heavside Whitmarsh, M.D. aged 52.

N.B.—A fee of 1s. is charged for the insertion of Notices of Births, Marriages and Deaths.

THE MORLEY CONVALESCENT HOME—Arrangements are now being made for the formal opening of the new wing. The ceremony will, it is expected, take place towards the end of next month or the beginning of March.

SOCIETY FOR THE STUDY OF INEBRIETY—Four lectures on inebriety and medical jurisprudence will be delivered by Dr Norman Kerr at the Medical Society of London, Chandos street, on Jan 10th and successive Tuesday afternoons.

MEDICAL MAGISTRATES—Mr George Augustus Davies, L.R.C.P. Lond., M.R.C.S., of Newport, Monmouthshire, and Dr George H. Dabbs of Shanklin, Isle of Wight, have been placed on the Commission of the Peace for the borough of Newport and the county of Southampton respectively.

THE NEW PUBLIC HOSPITAL FOR FALMOUTH—The committee for this hospital have now in prospect a substantial sum for the building fund and a large amount in annual subscriptions, so that they are in a position to invite building plans for the proposed institution. Some difficulty, however, has arisen with regard to the site.

FOOT AND MOUTH DISEASE IN LONDON—Although cases of this disease have not been discovered in the Metropolitan Cattle Market, it is deemed advisable by the authorities connected with the Board of Agriculture that an immediate inquiry be made into the condition of cattle in all the London cowsheds. Also, as a measure of precaution, the market is to be thoroughly disinfected after business hours.

YELLOW FEVER AT CUBA—Advices from the English Consul at Santiago report the continued existence of somewhat serious mortality amongst the inhabitants of Cuba from yellow fever, although foreigners for the most part seem to escape the disease. A little time ago Dr Garcia of Santiago conducted some experiments on the effects produced by changes of temperature and humidity on patients affected with the disease. The results, though on the whole favourable, would appear to indicate the necessity of further inquiry, which Dr Garcia is still engaged in prosecuting.

THE CHOLERA REGULATIONS ACT—A case was heard in a London police court a few days ago in which a passenger was summoned for neglecting to carry out Sections 2 and 3 of the above Act, which required that information should be given of the address and destination of every passenger on an incoming vessel to the port medical officer of London. The matter is of importance, as the port sanitary authority have signified their determination to prosecute all persons who may be found violating the above-named whole some provisions of the Act in question.

ROYAL INFIRMARY AND LUNATIC ASYLUM CORPORATION, ABERDEEN—A special general meeting of the corporation of this institution was held on Dec 27th, 1892, when the Lord Provost Stewart presided. In the course of the meeting it was stated that the Jubilee fund of £30,000 with the accruing interest had been spent, and a resolution was passed to the effect that the directors be empowered to transfer from the general reserve fund to the building fund such sums as might be deemed necessary to complete the work of the new buildings. A resolution was also passed granting powers to the board of directors to reconstruct the buildings of the Aberdeen Asylum and to erect a new hospital in connexion therewith, at an estimated cost of £50,000, and to obtain by loans the sum required to carry out the plan.

METROPOLITAN ASYLUMS BOARD—The number of patients remaining in the several fever hospitals of the Board at midnight on Jan 3rd, 1893, was as follows:—Eastern Hospital 284 scarlet fever, 61 diphtheria and 35 enteric fever, North Eastern Hospital, 402 scarlet fever, North Western Hospital, 316 scarlet fever, 98 diphtheria and 12 enteric fever, Western Hospital, 267 scarlet fever, 33 diphtheria and 13 enteric fever, South Western Hospital, 272 scarlet fever, 62 diphtheria and 19 enteric fever, South Eastern Hospital 305 scarlet fever 19 diphtheria and 12 enteric fever, Northern Hospital, 736 scarlet fever and 10 diphtheria, Gore Farm Hospital, 616 scarlet fever. At the London Hospital and at Guy's Hospital there were three cases of enteric fever respectively, and one case in Charing Cross Hospital. Thirty seven cases of small pox were under treatment in the wards of the hospital ship *Atlas*.

A NEW INFIRMARY FOR LANCASTER—The committee of this institution have decided to erect a new infirmary, at a cost of £17,000, at Springfield park. Mr James Williamson, M.P., recently gave £5000 for this purpose, and Mr W. Smith, M.P. (the president), has undertaken to build the children's ward at a cost of £1000. Including sums promised, there still remain about £4500 to be raised towards the total cost.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

PUBLISHER'S NOTICE

IN order to facilitate the work of reference to the volumes of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together.

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET.

"THE LANCET" DURING 1892.

THE following particulars of the work of THE LANCET during the past year have been forwarded to us by a correspondent and as they are likely to prove of interest to our readers we after categorically verifying the accuracy of the figures, publish them. From the figures submitted it appears that in the year 1887 THE LANCET contained 11,744 columns in 1888 it contained 12,376 in 1889 13,728 columns, in 1890 it rose to 14,032, and in 1891 the figure reached was 14,804 columns. The year 1892 shows a still higher figure—a total of 14,784 columns, 5992—within eight of 6000—of which were devoted to purely literary matters, 8892 columns contained advertisements, and space amounting to over 100 columns was required for the purpose of an index. From these figures a simple calculation will show that the average size of each weekly impression has amounted to 142 pages. Looking at the impressions individually, it will be found that one of the numbers contains 216 pages—namely, that of Sept. 3rd. No single number of THE LANCET of corresponding size has ever before been offered to the subscribers. Of the other numbers one consisted of 200 pages one of 168 pages, there were two of 152 pages nine of 144 pages, twenty five of 136 pages, twelve of 128 pages and one of 120 pages. The

columns of literary matter include reports of clinical lectures extending over 634 columns, 861 columns have been devoted to Clinical Notes and Original Articles, and the cases recorded in the "Mirror of Hospital Practice" required 198 columns. The columns devoted to Analytical Records this year amount to 29 and 49 columns have been used for notifying New Inventions. Annotations have taken up 761 columns and leading articles have reached over 431 columns, while special articles have extended to 951 columns. About 190 columns have been devoted to the interests of public health, and reviews and notices of books occupy 200 columns. Correspondence has received space to the amount of 289 columns and the answers to correspondents required 265 columns, miscellaneous medical news covers some 317 columns of THE LANCET. Further, the Students Number contained 156 columns devoted to information concerning the regulations and arrangements of the various medical schools and examining bodies. Notices and reports of the British Medical Association have occupied 70 columns, the reports of the General Medical Council amount to 23 columns, 51 columns have been devoted to Obituary notices, and 46 columns to Foreign and University Intelligence. special lectures have occupied 6 columns. Thus 5475 columns of matter have been accounted for, and the remaining 517 have been taken up with Special Supplements reports of medical societies, law cases and Parliamentary news of interest to the members of the profession, the Services, THE LANCET Sanitary Commissions, pharmacology &c. &c.

ANASTASIO CHINCHILLA

To the Editors of THE LANCET

SIRS,—I am anxious to know if there is an English edition of the works of Anastasio Chinchilla, especially of his "Anales Históricos de la Medicina en General y Biográfico—Bibliográficos de la Española en particular," which was originally published in Valencia by Lopez and Co in 1841-8. *El Siglo Médico* of the 25th inst. contains a short biographical notice of the author, which however, deals only in generalities. Can any of your readers oblige by supplementing the information?

I am, Sirs, yours truly,

Cavendish row, Dublin, Dec. 30th, 1892. GEORGE FOY, F.R.C.S.I.

THE LATE DR. WALSH.

OUR attention has been called to what appears to have been an omission in our obituary notice last week of the death of Dr. Walsh. During the later years of his life Mr. Buckston Browne was a frequent professional attendant on the late esteemed physician and it is the belief of his friends that to Mr. Browne's assiduous care in the surgical management of the case is due the prolongation for some years of the life of Dr. Walsh. We may also note that in our leading article on "Richard Owen and Walter Hayle Walsh" (THE LANCET, Dec. 24th, 1892) it was stated that he studied physical diagnosis under Laennec. This is an error. He was too late in Paris for this advantage, but through Louis and his other great teachers he came very near it.

THE ROYAL COMMISSION ON VACCINATION

To the Editors of THE LANCET

SIRS—Can you kindly give us any information with regard to the expense the country will incur with respect to the Royal Commission including the costs of the increase of small pox? Are the Commissioners paid per diem or is it contract work—in other words, paid according to the amount of the harm done? It does seem strange after all the profession has done to mitigate disease and suffering that a Commission, some of whose members belong to the profession should be instrumental in rendering those efforts abortive.

I am Sirs, your obedient servant,

St John's Worcester Dec. 26th, 1892

WM WOODWARD, M.D.

. The members of the Royal Commission on Vaccination are not paid. They give their services gratuitously. Whilst we regret that the lengthened period during which they have been sitting should have been utilised by many as a reason for disobeying the law, it must be remembered that since so much time has been allotted to the anti-vaccinationists to state their case it is most important that nothing should now be done to prevent an adequate reply being made to their contentions. This reply is now in progress and it is hence undesirable just at this moment to urge the Commission to act without fully hearing the answer of the advocates for vaccination.—ED L.

THE VITALITÉ BATH MAT

WE have had brought under our notice a novelty in the shape of a mat for use in the bath room and the nursery. The device has been introduced by the Vitalité Sock Company and consists of a mat of absorbent material—the well known loofah, in fact—which forms a good substitute for the cork ordinarily in use for that purpose. Its fibrous nature will recommend it from a sanitary point of view. It will undoubtedly be found an agreeable auxiliary to the comfort of the morning bath.

PROVISIONAL SPECIFICATION 15,482 192

V I R O L.

Cod Oil assuredly superseded at last, and by a very palatable congener—VIROL.

VIROL is a highly concentrated "Complete Food," consisting of the proteids, fats and salts of Beef and Eggs (including the Lime salts of the shell) and the marrow of Beef Bones, in proportions carefully adjusted to diet formulæ laid down by the leading Physiologists.

A DIRECT CHANGE IN CONCENTRATED MEAT-FOODS,

HAVING for its basis fifty per cent of the pure UNCOOKED JUICE of some of the CHOICEST BEEF OF THIS COUNTRY (Liquor Carnis), combined with other food substances, and prepared without the coagulation of the valuable albuminoids and consequently non-development of the meat aromatics, so obtaining a product—Malto-Carnus—rich in Beef Juice, yet entirely free from the smallest gustatory evidence of meat

THE LIQUOR CARNIS CO.

On and after the 1st of the New Year our revised rates of supply to Medical Men and Benevolent Institutions come into force. We therefore solicit applications for copies and samples.

HOSPITALS ETC.

The LIQUOR CARNIS CO., Ltd., 55, Holborn Viaduct, London, E.C.

SOLUBLE TABLETS

OF SPECIAL CONVENIENCE TO THE PHYSICIAN AT THE BEDSIDE OF THE PATIENT

The Physician at the patient's bedside has neither time nor apparatus to accurately measure or weigh the alkaloids powders he may desire to use, and he is, therefore, in a position to appreciate the availability of every device calculated to simplify the accurate exhibition and application of extremely active therapeutic agents.

The great advantage of TABLET TRITURATES is their adaptability to this purpose. Our line of these articles comprises nearly 1000 formulæ.

ARSENITE OF COPPER, TABLET TRITURATES.

Recommended in Bowel Affections, and especially in the Diarrhoea of Typhoid Fever

The 1 100 grain Tablets afford a convenient method of preparing the Solution. Dr Aulde, however, has since found administration of a Tablet containing a single dose more exact and expedient, and we therefore supply also a Tablet containing a dose of 1 5000 of a grain.

ANTISEPTIC TABLETS.

For quickly preparing Antiseptic Solutions and Washes

Each of the Tablets contains 1½ grains of Corrosive Sublimate with 87 100 grain of Citric Acid. The Citric Acid renders the solution of Corrosive Sublimate more active, permanent, and soluble, while from the Tablet thus presented may be prepared a solution of known strength. Put up in glass bottles of 1000 and glass bottles of 100 each.

ANTACID TABLETS COMPRESSED.

Each Tablet contains 3½ grains Precipitated Calcium Carbon, 2½ grains Magnesium Carbon, 1 grain Sodium Chloride. Prepared after the formula of Sir W. R.—, M.D., F.R.S., who, in the PHARMACEUTICAL JOURNAL AND TRANSACTIONS for August 24th, 1889, has pointed out the use of antacid remedies in dyspepsia and gravel. A reprint of Dr R.—'s paper will be furnished upon application.

We also manufacture a full line of HYPODERMIC TABLETS which are readily soluble, accurate, and permanent.

COMPLETE FORMULA LIST OF OUR TABLETS FREE TO MEDICAL MEN

A NEW DEPARTURE IN PILL COATING. ENTERIC PILLS.

At the suggestion of Wm. H. Flint, M.D., of New York, we investigated the feasibility of coating pills with a material that would resist the action of the gastric juice and yet be dissolved or disintegrated in the duodenum and intestinal tract.

To meet the desires of physicians in this direction we supply the following pills, containing medicaments whose action it is desirable to confine to the duodenum and lower intestinal region.

Arsenious Acid, 1 100 gr
Arsenious Acid, 1 50 gr
Calcium Sulphide 1 4 gr
Cathartic Comp., Imp.
Calomel, 1-4 gr
Calomel, 1 2 gr

Calomel, 1 gr
Calomel, 2 gr
Calomel, 3 gr
Corrosive Sublimate, 1 100 gr
Corrosive Sublimate, 1 50 gr
Corrosive Sublimate, 1 20 gr

Corrosive Sublimate, 1 16 gr
Corrosive Sublimate, 1-8 gr
Creosote 1 2 gr
Creosote 1 gr
Intestinal Antiseptic.
Mercury Bichloride 1 4 gr

Mercury Protiodide, 1 4 gr
Pancreatin, 1 gr
Podophyllin, 1-4 gr
Podophyllin, 1 2 gr

PARKE, DAVIS & COMPANY.

IDEAL NUTRIENTS. MOSQUERA'S BEEF-MEAL.

A predigested powdered meat, representing in actual nutritive value six times its weight of good lean beef. It is entirely devoid of all objectionable taste or smell and can be tolerated with ease by the most delicate stomach. As distinguished from any similar product heretofore known, it contains all the constituents of the meat, whether soluble or insoluble, in a condition ready for assimilation, while more than 50 per cent. of its substance is in a predigested form.

MOSQUERA'S BEEF-CACAO

Is a concentrated food consisting of Beef-Meal, a special grade of Dutch cacao and sugar in equal proportions. Beef-Cacao aside from the nourishment yielded by the cacao and sugar, both of which are valuable foods, possesses just one-third nutritive value of Beef-Meal. Mosquera's Beef-Cacao so completely disguises the taste of its proteid constituents that the palate cannot possibly detect their presence. It is especially valuable for invalids, convalescents and dyspeptics who have a natural dislike for, or are tired of, meats or soups and broths of a meaty flavour. It makes a delicious beverage which the medical profession will find invaluable in all cases as above stated.

MOSQUERA'S BEEF-JELLY.

Until the discovery by Vicente Marciano that plants of the natural order Bromeliaceæ contained a proteid digest ferment there had never been prepared a palatable peptone. The medical profession have long felt the want of such an article particularly for rectal alimentation, and in cases of extreme emergency, where a rapidly assimilating food was absolutely necessary to the life of the patient. In Mosquera's Beef-Jelly we are enabled to present a soluble preparation containing all the nutritive constituents of beef, and entirely devoid of the objectionable bitterness and disagreeable odour that has heretofore characterised products of this nature.

Information as to these preparations and their administration, samples, and reprints of articles reporting the clinical experience of physicians of eminence who have thoroughly tested them, will be furnished on request.

Lettsomian Lectures

ON

SYPHILITIC AFFECTIONS OF THE NERVOUS SYSTEM

Delivered before the Medical Society of London on Jan 9th, 1893,

By JOHN S BRISTOWE, M D LOND,
LL D EDIN, F R S,

CONSULTING PHYSICIAN TO ST THOMAS'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—My first duty is to thank you, and I thank you very sincerely, for the honour you have done me by appointing me your Lettsomian lecturer. But being profoundly sensible of the fact that the honour entails responsibility I feel bound to tender an apology for the temerity of which I have been guilty in choosing for my subject a disease of which my experience has been small by comparison with that of some of my auditors and which has been so well discussed from different points of view by my predecessors—Dr Broadbent, Dr Gowers and our distinguished President. My excuse is that while on the one hand my choice was made hastily and without due consideration on the other hand syphilis is a disease of vast and ever growing interest. It is one of which I have seen a good deal in its constitutional forms and to the study of which I have given time and thought, and I propose to treat of it mainly in its relations to the nervous system and from the clinical standpoint, and by the discussion of cases that have come under my own observation and have been interesting or instructive to me. I trust I shall not be deemed irrelevant or tedious if before entering on my special theme, I venture to place before you a brief statement of the views I entertain with respect to the pathology of syphilis. I do not pretend that these are in any sense novel. Still it seems to me that it may be convenient and conducive to clearness of apprehension if, in dealing with this complex and protean disorder I begin with such a sketch of it as will serve to indicate the lines of thought which will run through my lectures to define my position in regard to the cases which I shall bring under your notice and to obviate the need of subsequent explanatory interpolations. I regard syphilis, as I suppose all educated medical men do at the present day, as a specific infective disease due to the invasion and proliferation of specific living organisms and as having manifest relations to other specific infective diseases, but more especially perhaps to small pox and the exanthemata, to tuberculosis and leprosy and to malignant neoplasms such as cancer and sarcoma.

The clinical history of syphilis is briefly as follows—

1. At the spot on which the disease is inoculated a hard tubercle is slowly evolved and almost coætaneously the lymphatic glands next above it become enlarged and indurated, both probably attaining their full development, without any attendant constitutional disturbance, in the course of from six to eight weeks. These phenomena collectively constitute the first stage of the disorder or primary syphilis. 2. The disease may come to an end at this point, but usually and in the natural course of events, between six and eight weeks after inoculation constitutional symptoms almost suddenly declare themselves a febrile rise of temperature takes place, a rash appears over the skin and fauces and other tissues and organs not improbably become equivalently affected. This stage of the disease usually varies in duration from a week or two to several months, but occasionally lasts much longer, and may even recur from time to time for several years. It corresponds to the generalisation of the syphilitic poison and of its effects and is known as secondary syphilis. 3. With the subsidence of this stage the disease itself in most cases comes to an end, but not unfrequently—sometimes while the secondary symptoms are yet in progress, sometimes shortly or immediately after their disappearance, sometimes after an interval of many years, and may be during an interval of apparently excellent health—a further series of phenomena manifest themselves. These are the tertiary symptoms and constitute what is known as tertiary syphilis. The lesions of this stage, unlike the rash of the second stage, are for the most part unsymmetrical in their arrangement, originate as

it were capriciously in different organs, or it may be in only one, and tend to spread locally. They are essentially of the same nature as the primary chancre and result for the most part in grave and irreparable destruction of tissue. 4. Further, syphilis is often transmitted from one or other of the parents, or from both, to the fœtus, either *ab initio* or in the progress of its development, or at the time of birth, and thus the child is born infected with the virus of the disease, which sooner or later reveals its sinister presence by the evolution of morbid phenomena which correspond to those of the secondary or tertiary stage of acquired syphilis in the adult, but present marked special peculiarities. This is known as congenital syphilis.

I will now briefly compare syphilis severally with small-pox, tuberculosis and cancer. 1. The resemblances between syphilis and small pox are obvious, especially if we have regard to small pox caused by inoculation. In both diseases specific lesions appear at the points of insertion, and are attended with concurrent specific affection of the neighbouring lymphatic glands, in both, after the lapse of fairly definite periods of time, during which as a general rule the patient's health remains unimpaired, characteristic constitutional disturbances almost suddenly arise, and in both, after a longer or shorter time (supposing the patient does not meanwhile die), the constitutional symptoms subside and health tends to be restored. Furthermore, in either case the disease proves to be in a greater or less degree self protective, and in either case it may be imparted by the mother to the fœtus. But there are also striking differences, the most important one from my present point of view having relation to the degree and quality of the protection which they severally afford. In the case of small pox the specific virus at the end of a few weeks disappears absolutely from the system, and not only is there left behind no tendency to relapse or recrudescence of the disease, but also the patient enjoys almost absolute immunity from subsequent attacks on re-exposure to contagion. That syphilis is also in some sense self protective is proved not only by experiment and observation, but also by the fact that the secondary stage tends to and often does, subside spontaneously, but, on the other hand, relapses are not uncommon, and, what is far more remarkable and distinctive, notwithstanding the subsidence of secondary symptoms the specific poison of the disease is apt to lurk in the system, dormant yet potential, and ready, under conditions as yet unknown to us, to become again aggressive and to cause serious, though for the most part localised, outbreaks.

2. The relations of syphilis to cancer seem to me quite as striking as those of syphilis to small-pox. We do not at present know whether the cause of cancer is a specific parasitic organism or whether it is a specific organism evolved out of the living tissues of the sufferer. We know, however, that the disease is specific, that having once appeared in any spot its subsequent behaviour is that of an aggressive parasitic disease, that in the natural order of events the lymphatic glands next above the primary tumour become the seat of growths identical with it, and that subsequently the disease becomes generalised and tumours appear from time to time in various parts of the body, until at length the patient succumbs. The differences are, mainly, that we have as yet no sufficient grounds for believing that cancer originates in contagion or is derived from without, that its generalisation is not, so far as we know, attended with sudden febrile disturbance and widespread or symmetrical distribution of specific lesions, but that rather it resembles in its progress the tertiary period of syphilis. Another point of difference is that while at the point of primary inoculation of syphilis a single chancre only arises, in cancer the disease spreads locally, partly by continuous invasion, partly by the development of outlying nodules. It is interesting to note, however, that tertiary syphilis shows the same tendency to local spread.

3. Now as to syphilis and tubercle. The lesions in both diseases are what pathologists term "granulomata" and are often remarkably alike in appearance—as, for example, tuberculous and syphilitic tumours of the brain, tuberculous and syphilitic tumours of the lymphatic glands and lupus and certain cutaneous syphilides. Tubercle, like syphilis is an inoculable disease, may undergo generalisation, and may remain latent in certain parts of the organism with the liability to unexpected and sudden recrudescence. Its inoculability is proved by experiment on the lower animals and even by the frequent inoculation of Peyer's patches through the swallowing of infected sputum from the lungs. At the same time the disease is spread in the majority of cases by

means of infected air or food. That the contagium of tubercle is capable of generalisation, as are the contagia of small pox and syphilis is shown in the common production of general military tuberculosis by inoculation of the lower animals and by the cases not unfrequently met with in the human being in which patients die as of an acute fever in consequence of the nearly simultaneous development of military tubercles throughout the organism. But, on the other hand, these are exceptional cases, and tubercle is to a large extent a local disease and remains localised. This tendency to localisation is observed in the case of lupus, which for years may continue to spread over the skin and yet never be followed by tuberculosis of internal organs, in the case of scrofulous glands in the neck and elsewhere, in the case of tuberculous peritonitis and even in the case of ordinary pulmonary phthisis, in each of which the disease may be, and often is, limited to the organ primarily affected. Still, in all such cases there is the possibility of generalisation, and we often meet with abundant evidence of its supervention. The tendency of tubercle to become quiescent, with the potentiality of assuming an aggressive character after some indefinite period, is not uncommonly illustrated in the course of clinical experience. Thus we may find an apparently effete tubercular mass in the lung become the centre of a swarm of military tubercles and at the same time the source of a fatal outbreak of tuberculous meningitis, or an old tuberculous kidney, which had long ceased to cause symptoms, the apparent centre of an explosion of tuberculous mischief.

It is obvious then that, while syphilis in its case-history, has close resemblances to various other diseases, it has striking characteristic features of its own which distinguish it from all others and especially that all its different stages do not correspond to all the different stages of those diseases to which it seems most closely allied. Further, syphilis, like all other specific infectious diseases, retains its specific quality throughout its whole career. In all its stages it is still syphilis and the specific lesions of its primary, secondary and tertiary stages, as also those of the congenital form of the disease, are all irritative or inflammatory growths determined by the actual presence in them of the specific living organisms which are its cause. Again, syphilis, like all other such diseases, has a specific proclivity to attack certain tissues and organs in preference to others, a proclivity which is largely determined by relative suitability of soil. And I take it that the differences in this respect which distinguish the secondary and tertiary stages are due simply to modifications in this suitability which have resulted from the protective or modifying influence exerted over the tissues during the former of these stages, and further, that the distinctive features of inherited syphilis are due in different degrees to the operation of the same cause, to differences of vulnerability of the foetal tissues as compared with those of the adult, and to interference with the developmental changes which are going on in early life.

It is very important for the accurate delimitation of syphilis to bear in mind that it, like other diseases, and indeed more than most, is apt to be complicated and obscured by other disorders and to be followed by sequelæ which though having no specific connexion with it, have been largely—and still are sometimes—regarded as essential parts of it. Thus formerly, and even in my own early days, before antiseptic treatment had been introduced and when cases of venereal disease were aggregated in special wards erysipelas, phagedæna and hospital gangrene were frequent recompaniments of primary syphilis, and even now such complications are not uncommon. But there is no doubt that these are not truly syphilitic, but are due simply to the accidental inoculation of the local sores with other pathogenic organisms. Precisely similar accidents are apt to attend the so-called natural cow pox as it appears in the cow, and hence the local lesions in that affection not uncommonly present much violence of inflammation—a phenomenon which has misled scientific anti-vaccinationists into the belief that the original cow pox was a virulent and untamed malady, instead of being, as pure inoculations prove it to be, a mild and comparatively insignificant disorder, and that when similar accidents attend ordinary vaccination they are due to the tendency of cow pox to revert to its supposed original malignancy. By sequelæ I mean not lesions arising out of syphilis and still harbouring the specific contagium and capable therefore of rekindling or spreading the disease, but morbid conditions due to damage inflicted on regions or tissues by the direct influence of the specific poison, but remaining over as it were after the

specific element has died out. I refer to such conditions as lardaceous changes in various organs, damage inflicted on the bones of the head and nose, on the eyes and ears and probably also a constitutional weakness of certain tissues, rendering them unduly liable to degenerative and other changes and to the influence of other morbid poisons.

Before completing this introductory part of my lectures I should like to make a few remarks on the communicability of syphilis. So far as we know it is only imparted by direct inoculation, and is contagious therefore in the restricted meaning of that term. At the same time the contagium of the disease is presumably an extremely minute living organism and infests the specific sores and their discharges, and it may be worthy of consideration whether it might not under certain conditions—as, for example, when the mouth and throat are the seat of disease—be communicable by the breath or through the air. There is no doubt that we meet with cases of constitutional syphilis the source of which appears to be inexplicable. That it is usually imparted by inoculation of the sexual organs is in a sense an accident, due largely to the fact that the primary sore is not in all its stages necessarily a cause of serious discomfort to its owner or preventive of sexual congress, and that in the act it becomes freely applied to a delicate, readily inoculable mucous surface. If the local manifestation of cow pox extended over as long a period as a chancre does and were attended with as little intensity of inflammation there is no reason why cow pox might not be perpetuated as a venereal disease.

Judging from the analogies afforded by other infectious febrile disorders, and from pathological observation, it may be assumed that the syphilitic virus accumulates, not only in the primary sore and indurated glands, but also in all the secondary lesions, including those of the skin and mucous membranes and in the localised growths of the tertiary stage, and that equally from all of these successful inoculations might be made. It may be assumed also that during the secondary stage, when the virus is being distributed by the blood, this fluid and tissues which are not liable to be, or are not, the seats of specific implication are also infective, though, for obvious reasons, much less potently and much less certainly infective than are the parts wherein the virus has taken root and is growing. During the primary stage, however, and during the period of quiescence which often separates the secondary from the tertiary stage and even during the continuance of tertiary symptoms, the blood and tissues not specifically affected probably remain innocuous. It is of course indisputable that, during its primary and secondary stages, syphilis is virulently contagious, and the explanation is obvious. But it is, I believe largely held that syphilis in the tertiary form is not contagious. This I cannot admit. I am free to acknowledge that syphilis in this period of its career is far less frequently communicated than it is at any other stage, but this is due to the fact that the specific lesions are at this time, as in the first stage, localised, and for the most part so localised (often in internal organs) as to afford little if any opportunity for successful inoculation.

I will venture to quote briefly two cases which, though perhaps they may not be generally regarded as absolutely conclusive on the point, seem to me to constitute a weighty indictment against the innocence of tertiary syphilis. The first was a very sad case. A young medical friend of mine, a man of undoubted respectability and honesty, married a young lady of unimpeachable character and wholly free from taint of inherited syphilis. This was three or four and thirty years ago. He was at the time, and had been for some years previously (during which time I had known him), in excellent health. But I was aware that during all this time one of his testicles had been enlarged, and occasionally had troubled him a little. I do not think he even consulted me about it or that I ever saw it, but he spoke of it occasionally, and attributed it to an injury he had received some years before while riding. His wife, shortly after marriage, became *enceinte*, and when about half the time of pregnancy had been accomplished she became covered with an abundant and quite typical secondary syphilitic rash, which subsided in the course of two or three months under specific treatment. The foetus died in utero about a month before the full time, and was born with abundant evidence of syphilitic disease. She remained free from rash until, after a few months, she became pregnant the second time, then at about the corresponding period the symptoms of secondary syphilis recurred and again subsided under appropriate treatment. The second child was born at term and appeared fairly healthy, but

within a week or two developed severe constitutional syphilis and died therefrom when it was six weeks or two months old. The mother died a few weeks afterwards from phthisis of which she had first shown symptoms during the latter part of her first pregnancy. She had never previously manifested any phthisical tendency and all her immediate relatives were and have remained free. I think there can be no doubt that disease localised in the enlarged testicle was the source of contagion. The second case also concerns an old friend of mine. A married man, who has never had any family, inoculated himself accidentally with syphilis. Within less than a year the disease affected his brain and he became hemiplegic. He recovered, however, in the course of a few months and has remained free from specific symptoms ever since, and is in a sense fairly well. About seven years afterwards his wife, who had never shown any signs of such disease previously, consulted me for a characteristic attack of syphilitic roseola and sore-throat. From this she recovered quickly under the influence of iodide of potassium and mercury and she remains well. I may add that the gentleman's disease was not of the genital organs, and that not a shadow of suspicion rests on the wife's character.

In endeavouring to arrange the material which I wish to bring before you in such a manner as to render it interesting I confess that I have experienced some difficulty, partly because, while syphilitic lesions of the nervous centres fall into several well marked categories, the symptoms resulting from them are by no means always or even generally so far distinctive as to allow of non fatal cases being arranged in corresponding groups, and partly also because we cannot always be sure even when aided by post-mortem investigation, that the cases which we are disposed to regard as syphilitic are really syphilitic or conversely. I propose not to meet these difficulties and overcome them, but to evade them, and this I shall do somewhat roughly—first, by dealing for the most part with fatal cases and considering them as far as possible under the heads of syphilitic disease of vessels, gummata and inflammatory infiltration of tissues, secondly, by discussing instructive or interesting cases which did not prove fatal or in which the diagnosis was not verified by post mortem examination, and by interpolating or adding such remarks or comments as the cases themselves suggest.

Syphilitic arterial disease has been for many years past a well recognised affection. None of the arteries are, so far as I know, exempt from liability, although, according to our present knowledge, some suffer in larger proportion than others. Both the aorta and the pulmonary artery may suffer, as also may any of the systemic branches sufficiently large to have received distinctive names, and there is abundant reason for believing that the smaller and even microscopic arteries are at least as vulnerable as their larger relatives. The syphilitic process may involve the entire thickness of the vascular walls, but it commences in the inner or outer coat and always mainly implicates one or other or both of these. I suspect that its not infrequent commencement in the inner coat is due to direct inoculation by virus circulating in the blood, and am inclined to agree with Mr Hutchinson that when the outer coat suffers primarily it is from the fact that the vessel has become involved in lesions originating in the vicinity. Syphilitic disease causes thickening and irregularity of vessel, with tendency on the one hand to aneurysmal dilatation and rupture and on the other to stenosis and more or less complete obstruction by thrombosis. The consequences which would naturally follow such conditions are derangement of circulation and impairment of nutrition in the parts to which the diseased vessels are distributed, with on the one hand softening or some equivalent change, and on the other hand hæmorrhage, either from the rupture of a diseased vessel or in connexion with diffused degeneration of tissue. It is curious that although these syphilitic lesions are occasionally widely distributed they usually occur in limited districts the vessels elsewhere remaining wholly or for the most part healthy. Before proceeding to quote characteristic cases of the association of cerebral symptoms with syphilitic lesions of cerebral arteries, I will venture to bring before you three cases in which no doubt there were either central nervous lesions or symptoms referable to the nervous centres but in which there were of secondary if not trivial importance. Their main interest indeed depends on the fact that they furnish admirable illustrations of the characters and consequences of advanced syphilitic arterial disease.

The first of these was brought before the Pathological

Society by Dr Walter Edmunds on May 3rd, 1892.¹ The patient was a man aged thirty six, who came under Sir William Mac Cormac's care on account of an aneurysm on the right side of the neck, which had been rapidly increasing in size. He had a few days before admission been seized with a sudden attack of faintness, and after admission the mere handling of the tumour frequently brought on similar attacks. Owing to this circumstance, to the belief that his arteries were extensively diseased (for no trace of pulsation could be felt in any of the arteries of either upper extremity, and there was a loud basic systolic murmur), and to the fact also that the patient was exceedingly ill, it was decided not to attempt any operative procedure. I was consulted in the case and concurred in this decision. The patient had had well marked syphilis twelve years previously. He died comatose twelve days after admission. The heart was large and the pericardium adherent by easily broken-down adhesions. The valves were healthy. A gumma about two inches in diameter projected from the groove between the right auricular appendage and the pulmonary artery. The whole of the thoracic aorta, including the arch, was enormously thickened, all the coats being involved, but the outer coat much more so than either of the others. In places they were collectively more than eight times as thick as natural. The thickening extended along the innominate and right subclavian, the latter of which would only admit of the passage of a bullet probe. The right common carotid was healthy, but the right internal had springing from it near its origin a globular aneurysm about two inches and a half in diameter. The left common carotid was diseased and only admitted a bullet probe, and the left subclavian about an inch from the aorta ended in an impervious fibrous cord. The cerebral and abdominal arteries were all healthy, and no other visceral syphilitic lesion was discovered.

The second case was exhibited before the same Society and on the same evening by Dr Herbert Hawkins. It was that of a girl aged eleven who was admitted into St Thomas's Hospital suffering, it was supposed, from acute nephritis. After experiencing one or two short attacks of illness, probably due to infarction of the lungs, she was observed on Feb 7th to have swollen and cold legs and a few days later swelling of the face. She was admitted on the 20th being at this time extremely ill. She had general dropsy, was passing very little urine, which contained a small quantity of albumen but no casts, and there was evidence of pulmonary congestion. Subsequently she passed a little blood on one occasion with her urine, which continued to be for a time very scanty, but during the last four days of her life it became fairly abundant and ceased to be albuminous, the lower part of her lungs became solid, her pulse of high tension, she presented the Cheyne-Stokes breathing and died (apparently from uræmic poisoning) on March 2nd. At the post mortem examination gross disease was found in nearly all the arteries of the body. The first part of the aorta was studded with grey translucent spots and patches from the size of a split pea to that of half a crown, and for a length of three inches, immediately above the bifurcation the thickening was so great that the channel barely admitted a bullet probe. Similar patches were observed in the common carotids and subclavians, in the left internal carotid as it entered the cranial cavity and in the right internal carotid involving the origin of the middle cerebral. There was similar disease throughout the pulmonary arterial system. The renal arteries towards their entrance into the kidneys were completely obstructed by clots which were old and white at the periphery, but red and comparatively recent centrally. There was an old infarct in the kidney, but neither organ showed any evidence of nephritis. The liver presented a patch of ptenitic thickening and was rather large. The spleen was large and firm and its capsule thick and covered by old adhesions. The lower and back parts of both lungs were consolidated and contained large infarcts. There was hæmorrhage into each lateral lobe of the cerebellum, the clot in each case being the size of a hazel nut. No history of syphilis was elicited and the teeth were quite normal. There can be no doubt however that the lesions in this case were the result of congenital syphilis.

The next case is one which I exhibited before the Pathological Society on the 1st of April, 1895 as an example of aneurysmal dilatation of the coronary arteries of the heart. The patient was a sailor aged twenty two who was admitted to hospital for what was supposed to be fever to which paraplegia

succeeded, and who died at the end of three months apparently from exhaustion. The case was not under my care, and I can give no further clinical details concerning it. The pericardium was healthy. The heart was somewhat enlarged, and in the course of the arteries ramifying over its surface were observed a number of nodules, isolated and in strings, and individually from the size of a pea downwards, the nature of which at first sight was not very apparent. Dissection, however, showed that they were aneurysmal dilatations of the trunks and branches of the coronary arteries. In some situations the vessels presented an irregular sacculated condition, involving them from half an inch to two inches of their length, and in some instances continuous series of vessels were affected. The parietes of the dilated parts were thick, firm and apparently consisting of dense fibroid tissue. Some were empty, others were filled with adherent, tough buff coloured clots. The muscular walls of the heart and its valves were healthy, as also was the arterial system generally. There were several rather large patches of pulmonary apoplexy in the right lung. The liver and spleen were congested. The kidneys were of normal size, but the cortical substance of each was thickly studded with buff coloured patches and dark red-coloured tracts which seemed to have resulted from hæmorrhage occurring at different times. I described the brain and spinal cord as healthy.

I am not aware that at this time (thirty six years ago) any suspicion was entertained that the arterial system was apt to suffer in the course of constitutional syphilis, neither was it then the custom to examine the texture of the nervous centres so critically as has been done of recent years. Considering, however, that the patient died paraplegic, I have now little doubt that morbid changes might have been discovered in the cord had it been treated and examined by modern methods. No history of syphilis is recorded in this case, but there is also no reason to believe that any suspicion of syphilis was entertained while the patient was under treatment or that he was ever questioned on the subject. But I have for many years now regarded the specimen which I bring before you as a typical example of syphilitic disease of the coronary arteries and the case as one in which paraplegia was due to similar disease of the smaller arteries distributed to the cord.

In the following year Nov 3rd, 1857, Dr Peacock and I showed a case at the Pathological Society which seemed to me to be of singular interest. It was that of a pitman aged thirty five who had been admitted under Mr Le Gros Clark's care for hydrocele. This was tapped, and the testicle was then found to be much enlarged. Three or four days after admission he began to lose the use of his right arm and subsequently his speech became affected. It was then ascertained that six months before admission he had had a fit, followed by paralysis and failure of sight, from the effects of which he had in great measure recovered. The patient was now transferred to one of Dr Peacock's beds. At this time he appeared to be intelligent, but his speech was imperfect, his mouth was drawn to the left and he had almost completely lost the use of his right arm, but he could move his legs freely. There was no anæsthesia. The pupils were widely dilated, more especially that of the left eye, and scarcely responded to light. He could swallow solids, but not fluids. He improved a little for a few days. But twenty days after admission into the medical ward he had a fit and became comatose, in which condition he died two days later. The calvaria and dura mater were healthy, the subarachnoid fluid scanty. The large veins ramifying over the surface of the brain were distended with blood, but there was little capillary congestion. The substance of the brain was everywhere of normal consistence and colour. The ventricles contained but little fluid. The basilar artery in nearly its whole length was white, opaque and solid, its canal was occupied by a cylindrical body, the anterior extremity of which was rounded, while the posterior was bifid and formed a nipple like projection into each vertebral artery. The body was hollow and contained a little colourless fluid, but its parietes were tough and greyish and adherent to the arterial walls. The adhesions, however, were neither dense nor universal, and it seemed possible that there was space for a little blood to pass between them. The cerebral portions of the internal carotids had not more than half their normal diameter, and both they and their branches for a length of half an inch were blocked up by solid adherent coagula of old formation. All the other arteries at the base were healthy and contained either fluid blood or soft coagulum. The heart was large,

but its valves were healthy. There was a small hydrocele on the right side and the corresponding testicle was in a state of chronic inflammation. All the other viscera were healthy.

This case is remarkable from the fact that at the necropsy all the main arteries at the base of the brain appeared to be completely obstructed by old coagula, and the puzzle as to how the cerebral circulation and the normal consistence of the brain had been maintained seemed insoluble. I can only suppose that the brain had been imperfectly supplied through the agency of the partially obstructed basilar and the circle of Willis and that his final seizure was connected with some increase of obstruction taking place here at the time of his last fit. It seems odd to me now that I seem to have had no suspicion that the arterial disease was syphilitic, either when the case was exhibited or a year later, when I read before the same Society a paper entitled "An Analysis of Seven Cases of Obstruction of the Cerebral Arteries," in which I not only included this case but quoted two others with a definite history of syphilis and ventured to suggest of them that the arterial disease was syphilitic. It is true that no history of syphilis was obtained and obviously no suspicion of it was excited by the condition of the testis. I have no doubt now that the affections of the testis and of the arteries were both syphilitic.

One of my twosupposed syphilitic cases just alluded to is narrated at some length in the tenth volume of the Transactions of the Pathological Society, p 21. The patient was a steam packet engineer who was admitted to hospital on Jan 4th, 1859. He had had three fits, the first some years previously, the second eighteen months before admission and the last eleven days. He had continued to follow his employment (although after the second fit he had become liable to headache and vertigo) until the occurrence of the third, which was followed by partial left hemiplegia and indistinctness of speech. On admission he was still suffering from hemiplegia and thickness of utterance and appeared imbecile. While under treatment the imbecility increased and he became troublesome and spiteful and on one occasion threw his faeces at the Sister. On Feb 25th he passed into a comatose condition and remained thus for twenty seven hours, when he died. No history of syphilis was noted. At the post-mortem examination, however, the scars of ulcerated buboes in the groins were observed. On removing the calvaria the dura mater over the greater part of the upper and lateral aspect of the left anterior cerebral lobe was found to be thickened, rough, and a little congested, the corresponding surface of bone being rough and softened. The surface of the brain generally was healthy though a little congested, but the dura mater in the region before indicated and in an area of about eight square inches, was firmly adherent to it by means of a layer of fibroid tissue in which and partly in the subjacent brain were embedded two or three tough opaque white fibrous masses from the size of a hazel nut downwards, the grey matter corresponding to the adhesions was softer than natural and in places had wholly disappeared, in the anterior part of the left corpus striatum was an imperfect cyst, apparently of hæmorrhagic origin and about as large a hazel nut, the anterior half of the right corpus striatum was congested and much softened, the rest of the brain was fairly healthy, the left internal carotid and its branches for about an inch were buff coloured and looked atheromatous, and on slitting them up they were found to be filled with adherent cylinders of tough old conglum, the other vessels were healthy, the heart and lungs were normal, the liver was attached to the diaphragm by numerous old adhesions which corresponded for the most part to deep fissures in the surface of the organ, and these in their turn corresponded to cicatrix like tracts in the substance of the liver, embedded in some of which were small knotty tumours. All the other organs were healthy.

I remarked of the case that "it was exhibited chiefly in reference to syphilitic disease of internal organs which had been several times brought under the notice of the Society by Dr Wilks and other observers. The kind of deposit supposed to result from the syphilitic poison was recognised both in the liver and in the brain." Later, in the same volume, when I again referred to this case amongst my group of seven, I spoke of it and one other case, which I shall not now quote, in the following words: "In two of the cases the patients had suffered from well marked syphilis. Is it possible that the secondary cachexia of this disease is capable of producing the condition of cerebral arteries under consideration?" I may add that even at this time what are now known as gummata of internal organs were by no means

generally regarded as syphilitic, and that, so far as I know syphilitic disease of arteries was not recognised. Indeed, I may point out, as showing how little this latter lesion was suspected of having any association with syphilis, that even our President, in his excellent article on constitutional syphilis, which appeared seven years later in "Reynolds' System of Medicine," makes no allusions whatever to the subject.

In the sixteenth volume of the Transactions I published another case J C—, a carpenter aged twenty seven, came under my care on May 2nd, 1863. He had contracted syphilis four years previously and had had secondary eruptions at intervals since. He had been attacked four days before admission with pain in the head and giddiness without loss of consciousness, and at the same time lost power in the right arm and in the legs. On admission he was quite sensible, but his speech was imperfect. He complained of giddiness and of aching in the shoulders. His right arm was powerless and his mouth was drawn to the left. His legs appeared fairly normal. There was no anæsthesia or affection of the special senses and his pupils acted to light. He became drowsy some days after admission, but there was no material change in his condition until the morning of the 16th, when, after complaining of pain in his head, he suddenly became insensible. He never recovered complete consciousness, but would now and then respond by opening his left eye when shaken or spoken to loudly. The pupils were equal and acted to light. The left arm lay limp and entirely without motion, but all the other limbs, including the previously paralysed right arm, presented occasional slight convulsive movements. During the last few days of life he was completely comatose, his convulsive movements ceased and his eyes became divergent. He died on May 28th. The skull and dura mater were healthy. The arachnoid was somewhat opaque and there was a little turbid fluid in its cavity. The pia mater was slightly congested. The arteries at the base were healthy with the exception of the right middle cerebral, which was completely obstructed by a firm decolourised clot. The middle lobe of the right cerebral hemisphere was softened and the grey matter in parts congested, in parts paler than usual and yellowish. The left corpus striatum presented a cavity about one-third of an inch in diameter containing turbid fluid and bounded by vascular walls. The heart was healthy, the lungs pneumatic in the lower lobes. The capsules of the liver and spleen were thickened in patches, but otherwise these organs were normal. The kidneys were small, and presented a few irregular depressions on the surface. I remarked of the case that it was interesting as furnishing an example of obstruction by clot of one of the middle cerebral arteries without any discoverable source of embolism, and from the fact that the patient had, to within a short time of his last illness suffered from syphilis, which I had already shown to be a not improbable cause of such obstruction. I remarked, further, that the obstruction of the right middle cerebral must have been the cause of the sudden aggravation of symptoms, with paralysis of the left arm, which took place twelve days before death, and that his original attack of right hemiplegia must be associated with the presence of the cyst discovered in the left corpus striatum. It seemed to me doubtful whether this had resulted from hæmorrhage or softening, but I thought it probable that in either case it had been determined by disease of some of the minute terminal branches of the left middle cerebral distributed to the affected region.

Since the case just narrated was published, now nearly thirty years ago I have naturally seen many other cases of syphilitic disease of the cerebral arteries in some of which the arteries were alone implicated, in more of which the arterial disease was complicated with gummatæ and amongst them two cases under my care which were published as Cases 1 and 2 by Dr Greenfield in his communication to the discussion on visceral syphilis were recorded in the Transactions of the Pathological Society for 1877. But there is naturally a certain amount of sameness in cases of cerebral arterial disease, and I shall content myself therefore with devoting the remainder of this lecture to the consideration of a case or two in which the disease was limited to the basilar or its branches, and in which the pons or neighbouring parts had undergone softening. I published a paper on this subject in THE LANCET of July 7th 1883. The cases quoted therein were six in number of which only two were certainly syphilitic, but I strongly suspected, though I had no proof, that two or three of the others were of the same nature.

The first undoubtedly syphilitic case was that of a young

man aged thirty three who had contracted a chancre exactly six months before his death, and who was suffering from secondary symptoms in the form of psoriasis when his fatal illness seized him. Excepting for his secondary symptoms he had enjoyed good general health until within three or four weeks of his admission. He was then attacked with occipital headache which was followed in the course of two days by frequent vomiting. He was admitted on April 16th, 1872, at which time he was still suffering from headache and presented abundant traces of his syphilitic rash. Two days after admission he began to rumble a little and to be troublesome, and the next morning it was noticed that his pupils were contracted, his conjunctivæ congested, and his left eyelid dropped slightly. Five days later, when he awoke in the morning he was found to be hemiplegic on the left side, and after another four days it was noticed not only that the left lid still dropped a little, but also that there was paralysis of all the muscles of the right eye, excepting the superior oblique. Meanwhile the patient was becoming more and more drowsy and stupid, and he died the fourth day after the paralysis of the muscles of the right eye had declared itself—namely on May 2nd. Notwithstanding the fact that the first evidence of brain disease had shown itself in less than five months after he had contracted syphilis, it was naturally assumed that the patient was suffering from cerebral syphilis and he was treated accordingly. Further, it was not difficult to speculate from the symptoms as to whereabouts the cerebral lesion would be found. The left-sided hemiplegia pointed to involvement of the motor tract issuing from the right hemisphere of the brain, and that the part directly implicated was the right crus cerebri, or the contiguous portion of the pons, had been foreshadowed by the slight ptosis observed in the left upper eyelid. This surmise was confirmed when a few days later total paralysis of the right third nerve was added to the other phenomena. At the post-mortem examination there was found syphilitic thickening with obstruction by clot, of the right posterior cerebral artery, and consequent softening with more or less disintegration in patches of the right crus cerebri and of some of the neighbouring parts to which this artery is distributed. The paralysis of the right sixth was no doubt due to thickening of the membranes observed at the base of the brain, and the very partial paralysis of the left third was connected with some thickening of its trunk. It may be assumed that the patient's early and comparatively vague cerebral symptoms were caused by the disease of the arterial walls and slight associated inflammation of the membranes in the neighbourhood, that the hemiplegia took place when the channel of the posterior cerebral became suddenly occluded and that the right third nerve got involved as the area of softening extended. Beyond considerable excess of fluid in the ventricles there was no further sign of disease in the heart, the abdominal and thoracic organs were all healthy.

The second case was that of a young man aged twenty-seven, who had had primary syphilis about two years before the symptoms of cerebral disease arose. He was admitted under my care on Dec 24th 1881. For three weeks he had complained of pain in the frontal region, which had become more severe during the last two days. There had been no sickness. During the night of the 23rd he was seized with almost complete hemiplegia on the left side, associated with rigidity of the arm and leg inability to speak, and well-marked paralysis of the third nerve on the same side. On admission he was still partially unconscious, the pupils were dilated and equal there was an external strabismus of the left eye and ptosis of the left eyelid, the mouth was drawn slightly to the right, the tongue was protruded markedly to the left; he was unable to speak, but seemed to understand what was said to him and indicated that he suffered from pain in the frontal region no difficulty of swallowing, the left arm was flexed at the elbow and lay across the chest and the hand was closed, the whole limb was rigid and completely paralysed, the left leg also was rigid but extended and he retained slight power over the movement of the toes, the patellar reflex was brisk on both sides but more so on the left, no ankle clonus, plantar reflex almost absent on the left side, left leg colder than the right, no anæsthesia. The next day he had attacks of partial unconsciousness during which the head and eyes were strongly turned to the left. On the following day he manifested some return of the power of articulation, and was evidently not aphasic. All signs of paralysis of the left third portio dura and hypoglossal had disappeared and the paralysed arm and

leg had become limp. Three days later the urine, which from the beginning had had to be drawn off, had become alkaline and offensive, and on that day his temperature reached 103.4°. After this the pulse increased in frequency, the temperature rose irregularly, and on one occasion he had a prolonged rigor, there was a slight return of the paralysis of the left third, facial and hypoglossal, and the left arm and leg again became rigid. He then passed into a state of coma, and at the time of death (namely, noon Jan. 4th, 1882) his temperature had risen to 109.2°. The vessels of the pia mater were injected, but no trace of meningitis was discoverable. The posterior cerebral and some of the smaller arteries in the neighbourhood were much thickened, yellowish and opaque, apparently the seat of syphilitic disease, but the other and larger vessels were healthy. There was slight comparative softening of the left temporo-sphenoidal lobe, and the pons, which was somewhat smooth, was soft and semi-fluctuating. On incising this part an irregular patch of broken-down brain substance was found to occupy the greater part of its right half, being separated from the surface and from the surrounding healthy substance by a zone of congested and apparently inflamed tissue. The rest of the brain substance was normal. No other important signs of disease were found. The post mortem examination does not clearly explain the concurrence of left hemiplegia and slight paralysis of the left third, but, on the other hand, the softening of the right half of the pons accounts both for the left hemiplegia and the deviation of the eyes and head to the left. It is interesting in this case that while some of the larger arteries at the base were diseased they were not obstructed and that while the pons was the chief seat of softening the basilar artery was healthy. I suspect that in this case, as in some of the other cases I have quoted, where there was manifest syphilitic disease of arteries at the base associated sometimes with obstruction, and where patches of softening were found in regions with which these diseased arteries had no connexion the softening was due to obstructive disease of the smaller vessels ramifying in the softened district.

OPHTHALMIC KNOWLEDGE CONSIDERED AS ESSENTIAL TO GENERAL MEDICAL AND SURGICAL WORK¹

By R. LAWFORD KNAGGS, M.C. CANTAB.,
OPHTHALMIC SURGEON TO THE LEEDS PUBLIC DISPENSARY.

THE subject of ophthalmic knowledge in relation to medical and surgical work is not new, but the time is suitable and the subject itself is ripe for further consideration and review. By certain new regulations the Conjoint Board of the Royal Colleges of Physicians and Surgeons has decided that all students commencing professional study after January 1st, 1892, must have received three months' clinical instruction in ophthalmic surgery at suitable institutions before being admitted to the final examination. We may expect therefore that this new lead will be followed in other directions, and that before long the ophthalmoscope is likely to occupy a very much more prominent place in the ordinary practice of our profession than it has done hitherto. I shall not be considered censorious or inaccurate when I state my belief that the bulk of the profession engaged in general practice derives little information or assistance from the use of this instrument. Want of skill, want of time, imperfect knowledge of what can be learnt, and possibly inadequate remuneration for the time consumed in the investigations all contribute in divers ways to keep the ophthalmoscope in general practice very far below its capabilities. The investigation of ocular conditions has thus been handed over to a small number of men, and it has come to be regarded as not inconsistent with a reputation for sound general professional knowledge that the individual should candidly confess absolute ignorance of all pathological conditions of one of the most important, if not one of the most vital, organs of the body—an organ, too, in which changes associated with many common and important general diseases can be seen and watched *in situ* during life, whilst in the case of the larger viscera, which

we handle or palpate, percuss or auscultate, under the impression that we know all about them, the various alterations are much more largely matters of inference. No instrument probably since the introduction of the stethoscope has done so much to add to our general knowledge of disease, and none is more highly valued by those who have mastered its difficulties. My purpose now is to refer to a number of facts, nearly all of which can be illustrated by cases occurring in my own practice, to prove that the general practitioner should not consider a knowledge of ophthalmic medicine and surgery as outside his proper sphere, but rather that it should be the necessary complement of his professional knowledge. Many patients seek advice for general ailments, the only cure for which is the suitable correction of their refraction. Children in this way are often chronic invalids, till an observant schoolmaster, perhaps, detects their deficient sight, suitable glasses are provided and their recurring headaches and rhubarb and soda become from that time things of the past. The following instance will show how an important and, possibly, a serious mistake may result from so simple a matter. A child was admitted into hospital with some febrile disturbance and vomiting, complaining of its head and with an internal strabismus which had just appeared. When the physician went his rounds the probable existence of tuberculous meningitis was gravely discussed. As the child improved and the strabismus persisted the delusive quiescent period of that disease was not lost sight of. The child, however, remained so well that in a happy moment the ophthalmic surgeon was consulted as to the strabismus. It was due to hypermetropia. Such a case points the moral that every medical man ought to be able to distinguish between a paralytic strabismus and one due to hypermetropia, and that when a strabismus becomes a possible factor in a diagnosis its real nature should be decided. Mistakes in diagnosis are easily made and lead to errors in treatment in such cases, but it may be reasonably hoped that their numbers will diminish, for abnormalities of refraction are capable of immediate detection by ophthalmoscopic methods, which need the very minimum of skill and are quite within the power of anyone to acquire. The purulent ophthalmia of infants and the gonorrhoeal ophthalmia of adults are not liable to be overlooked. These serious diseases at once create anxiety and the medical attendant cannot release himself from his responsibilities, as he may prefer to do in less urgent matters.

In cases of phlyctenular ophthalmia and corneal ulceration, which he will frequently be called upon to treat if his practice is large, his responsibilities are not unimportant. The damage to vision from the irregular astigmatism produced by the corneal scars may seriously influence the choice of an occupation and the future prospects of the patient. As these ailments so frequently recur in the same individual and amongst the poorer classes, the practitioner is forced to deal with them, and it is important that he should know how to treat them well. He should not lose sight of the scrofulous diathesis with which they are so frequently associated, and should avoid measures for the local condition that would have a deteriorating influence upon the constitutional state. One point he should never lose sight of—viz., that if constitutional delicacy is a predisposing cause of the ailment refractive errors are often exciting ones. Another of the more common forms of eye disease with which medical men are familiar is interstitial keratitis. The evidence it may leave behind it, like the results of a symmetrical disseminated choroiditis, may furnish the clue to the existence of the syphilitic taint and in obscure conditions may have a diagnostic value. The discomfort arising from some of the ocular manifestations of syphilis may lead occasionally to the detection of the disease for the first time. Two persons presented themselves amongst my outpatients last week suffering from iritis. One was a woman who made no mention of a well marked secondary eruption with which her body was covered. When it was pointed out she attributed it to "change of life," and stated that she had had no advice or treatment for it. The other a young man, had contracted a venereal complaint not long before, and when he came with iritis was extensively affected with a severe syphilitic rash. He was undergoing no treatment and would have gone away without referring to it if its existence had not been sought for. These are cases whose real nature may easily escape detection. All who have studied syphilis as a whole should be familiar with its commonest manifestations in all the important organs of the body and know how to treat it both locally and constitutionally. But it is not only in syphilis

¹ The Presidential Address to the Huddersfield Medical Society, delivered Nov. 1st, 1892.

that iritis may occur, it may be produced by a deposit of "tubercles, which may be seen studding the iris. The prognosis is not very favourable. These cases left to themselves are more likely to end fatally from tuberculous inflammation of the meninges or other organs than to recover, so that if good is to be done the treatment must be decided and prompt. Fortunately this form of iritis is not common, but it is important that its gravity should be speedily recognised and that it should not be left till it is too late to interfere with any prospect of success. Many years ago Mr Hutchinson drew attention to the intimate connexion existing between certain cases of frequently recurring iritis and the rheumatic or gouty diathesis, and published a long series of cases in the Royal Ophthalmic Hospital Reports. This disease, which is one of the most troublesome and intractable forms of ocular inflammation, often seriously cripples those who suffer from it and may lead to more or less complete blindness. Where hospitals are distant and specialists unknown it is essential that the practitioner should distinguish and adequately estimate such conditions, so that he may carry out independently and intelligently a line of practice together with suggestions or hints that may come from those of greater ophthalmic experience.

With the introduction of the ophthalmoscope many pathological conditions were revealed within the eyes which experience has proved to be connected with, and often the result of, various constitutional diseases. The delicate and highly organised nervous and vascular layers of the fundus are, probably more than any other similar substance in the body, liable to be affected by diseases which seriously influence the nervous and vascular systems, and sight is so sensitive and of such value to the individual that any impairment of it is quickly detected by the sufferer and viewed with alarm. Thus it happens in many general diseases that the patient first becomes aware that something is amiss by the onset of defective vision. It is a pity that visual deficiencies do not attract more definite professional attention, for the custom is widely prevalent to go first to the optician for glasses rather than to the medical man for advice. If the optician has a fair knowledge of his business and is a conscientious man he frequently recognises at once his inability to help, but it is no uncommon thing to find much money spent on glasses, time wasted, and vision still further impaired before professional assistance is sought. For the intelligent use of the ophthalmoscope in general practice a certain amount of elementary knowledge is required. Without this appearances would often be misread or given rise to ideas that are vague or altogether mistaken, but when once this knowledge is acquired careful observation of the many intra ocular conditions that are to be met with in abundance in practice cannot fail to be highly instructive, to enlarge our grasp of disease and of pathological processes and to prove eminently useful towards forming a sound opinion. Not the least important part of this elementary knowledge is anatomical—viz. the ability to decide in what structure within the eye the visible lesions are really situated. Many men are able to use the ophthalmoscope without difficulty but are unable to give adequate reasons (anatomical ones, I mean) for ascribing certain conditions to the retina and others to the choroid. Consequently when they meet with appearances differing from those they have learnt to know by sight and labelled with a name they find themselves at a loss and unable to form clear and decided ideas about them. On the other hand, those who possess this knowledge and who are able to locate in the one or other structure and who are able to structure what they see have a sound foundation upon which they can build if they use their opportunities. The inflammatory and degenerative states and hemorrhages which are to be met with in the retina they will trace in most cases to some constitutional disease or diathesis. In the majority of instances some form of Bright's disease will be the cause. In some the existence of reinitis will be of value as an evidence of advanced disease, whilst in others renal disease may not be suspected until the ophthalmoscope reveals an inflamed retina as the cause of failing vision. Not long ago I saw a woman in whom well-marked retinal changes led me to detect diabetes, until then unsuspected, and I remember another instance in which a medical friend and myself were greatly assisted in our diagnosis by finding renal hemorrhages associated with diabetes and albuminuria. Sometimes pathological changes are seen in the retina in syphilis, in leucocythemia, in anemia, pernicious or simple, and in gout. Embolism of the central artery too causing sudden blindness in the affected eye and typical ophthalmoscopic changes may like

embolism of a cerebral artery, be one of the disastrous results of cardiac disease. Choroidal mischief has much less significance as an indication of constitutional disease than reinitis, yet it sometimes affords information that may prove of the greatest assistance. I am permitted to refer to a case that some years ago was sent into the Fever Hospital supposed to be suffering from typhoid fever. As time passed the diagnosis remained uncertain. Curiosity prompted me to ask to examine the eyes, and I saw what appeared to be choroidal tubercle. The necropsy proved the accuracy of this supposition and the final diagnosis of tuberculous meningitis was correct. I know of another instance in which the timely recognition of tubercle in the choroid of a patient who did not seem seriously ill enabled a diagnosis to be made of acute general tuberculosis and a professional reputation to be saved from damage. Nor must I omit to mention the frequency with which various forms of choroidal disease are to be found in the subjects of acquired or congenital syphilis. In a large number of instances affections of the optic nerve are closely associated with some disease which lies well within the province of medicine or surgery. Optic neuritis is sometimes to be seen in albuminuria and it may be one of the more serious signs of lead poisoning. In my case-books I have a note of a man with double optic neuritis from syphilis or such intensity as to cause complete blindness, but which, under vigorous mercurial treatment, recovered completely with normal acuteness of vision, and one of my dispensary patients still under treatment who came for failing vision due to papillitis in his only good eye had an unsuspected chancre and a secondary rash.

Optic neuritis is developed in various intra-cranial diseases, but in cerebral tumour it is one of the chief diagnostic signs. We may all think ourselves competent to diagnose so gross a lesion as a cerebral tumour but if we cannot use the ophthalmoscope we cannot do it without assistance. The surgeon of the future who may aspire to interfere with such growths will rightly deserve to be called "mechanical" rather than "scientific" if he is unable to arrive at his diagnosis without the co-operation of the specialist. Though primary atrophy of the optic nerve, as distinguished from post-neuritic atrophy, is also met with in plumbism, its chief interest lies in its connexion with sclerosis of the spinal cord. When a student I used to wonder that I never saw atrophied discs in the well marked cases of locomotor ataxia which were common enough in the wards and amongst medical out-patients. But now I know that what I missed there is to be found in ophthalmic clinics. Here cases of primary atrophy are of sufficiently frequent occurrence in which a suspicion, a probability, or an absolute certainty exists as to their association sooner or later with disease of the spinal cord. The length of time that such conditions take to develop serves to deprive many of these cases of a good deal of their interest in hospital practice. But in private practice it is otherwise. If the progress of the disease is slow the interest of the medical man is kept alive as in the course of years he sees certainty issuing out of obscurity. Many years ago my sympathy was aroused on behalf of a comparatively young man who had been stricken with blindness. In due course I came in contact with him professionally and witnessed attacks which the term gastric crisis aptly designates. Their cause seemed unfathomable. The blindness was due to optic atrophy and though the knee-jerks were still present I felt that these two interesting conditions had somewhere a connecting link. The patient's subsequent history may be full of interest for me, for I expect if he lives he will develop other symptoms which will leave the nature of his complaint no longer in doubt. Nor is atrophy the only ophthalmic symptom of interest in spinal cord diseases. Another case illustrates the transient paralysis of the ocular muscles which may be seen occasionally in the early stages. A female aged thirty five, recently under the care of a medical colleague for vague pains in the head and limbs after influenza, presented herself amongst my out-patients with paresis of the right third nerve which gradually increased and then improved, disappearing completely when after a couple of months a paresis of the left third nerve occurred. The duration of the second affection was only short. This patient had no knee-jerks and when I referred her to my colleague he was able to elicit a description of true lightning pains. We may meet also with paralysis of the muscle of accommodation as a sequel of diphtheria. Such a case came to me not long ago and with it there was paresis of the soft palate muscles which caused a nasal voice and permitted food to pass into the nose, the only remedy was the child's inability to read

that attracted its parents' attention. But the intricacies of the paralyzes of the ocular muscles and of such conditions as hemianopsia are so valuable as localising symptoms in cerebral disease and so complicated and difficult to remember that it is no small satisfaction to know that we can find very valuable information about them in Mr. Swanzy's Bowman lecture in vol. ix. of the *Ophthalmological Society's Transactions*. Ophthalmic complications of considerable interest are some times produced by the most common diseases. There is ulceration of the cornea that is occasionally seen with herpes zoster of the first division of the fifth nerve, and I may here notice a similar condition that may result when the same nerve is implicated in disease. Amongst my records I find a note of one case in which an atrophied disc and complete blindness were attributable to an attack of facial erysipelas, doubtless with orbital cellulitis, and only recently I had to remove an eye which was found completely disorganised when an erysipelatous swelling subsided and allowed the lids to be opened.

For the investigation of ocular conditions connected with pregnancy the general practitioner has greater facilities than anyone else. When they occur in connexion with eclampsia and albuminuria the great and pressing danger to life tends to throw the sight affection into the background. But there are states in which the damage to vision may alone require consideration. Thus lately I have followed the progress of a case, which I hope soon to record in detail, in which there was every reason to believe that pregnancy was leading slowly and insidiously to optic nerve atrophy and complete blindness. By the kindness of Dr. Braithwaite the patient was admitted into the Leeds Infirmary for the induction of premature labour. Vision that had fallen to such an extent that the fingers could not be seen began to improve directly the immediate effects of the labour had been recovered from and is now about one third of the normal standard. This result was the more gratifying to the patient and myself inasmuch as the other eye had been completely blind for years from atrophy which had come on in connexion with a previous pregnancy. Severe injuries often implicate the eyes, and important internal changes will take place within an eye as the indirect result of an injury in its neighbourhood. A conspicuous example of this not long ago left the Huddersfield Infirmary, where she was under the care of my father. A young woman was shot in the right temple, the bullet passing below the orbit, across the nasal fossa and lodging probably in the antrum of the opposite side. The bullet wound healed without the least trouble in a few days, but a remarkable series of changes took place within the eye as the result of the concussion. Inflammation of the ruptured choroid supervened in the yellow spot region and, in spite of vigorous treatment, it ended in a central detachment of the retina and a serious and permanent defect in the very centre of the field of vision. It was instructive to watch the downward progress of events within the eye until the climax was reached, and the observer could not fail to be impressed by the great difference in the reparative powers possessed by the various anatomical structures.

Cases to illustrate my subject could be multiplied in definitely. Note-books of ophthalmic work are full of instances in which ocular conditions have had to be traced back to states of health which he strictly within the domain of the general practitioner, and the treatment in many instances resolves itself into that which is needed for the general bodily state. The specialist, so-called, simply fills the gap necessitated by an incomplete professional curriculum, but the process, though it has its pleasures, is not without its inconveniences. It is hardly comfortable for any party concerned when a patient who has casually drawn the attention of his medical attendant to a cataract and been referred to a specialist because eye diseases are out of his province has to be returned to the care of his own medical man because he is found to be suffering from diabetes. Yet these things do happen and will from time to time repeat themselves, until ophthalmic medicine and surgery become essential parts of medical and surgical work. Practitioners with but little acquaintance with ophthalmic literature will perhaps feel a difficulty in knowing where to turn for information presented in the form that is most useful to them. Text-books cannot be arranged to suit all parties, and the association of ocular conditions with various forms of disease or injury does not receive the attention it deserves in those which most men have at their disposal. Thus in two popular text-books on Diseases of the

Eye I can find no reference in the indices to pregnancy, and the notice taken of it in the text is almost as meagre, and yet the ophthalmic conditions connected with pregnancy furnished Mr. Power with material for a long and interesting paper—"Diseases of the Eye occurring in connexion with Pregnancy"—some twelve years ago. The best text-book, after all, is the eye itself. Systematic and regular observation of the things that are written there will furnish much fruit. Books are the outcome simply of clinical observation, experience and thought, and any man who will take the pains to acquire the elementary ophthalmic knowledge necessary for accurate observation can by careful work store up many facts. Sir George Humphry reminds us that facts may be regarded as pegs whereon thoughts may be hung, and thoughts as the rivets whereby the pegs are fastened.

Park square Leeds.

LOCAL DEPLETION.

By JOHN BOYD, M.D. EDIN.

IN THE LANCET of July 30th, 1892, there is related the deplorable case of the Commendatore Giordani at Florence, who on the evening of the 14th, whilst walking in Vallombrosa, memorable from the reference by Milton, fell into a pit at the foot of an incline and was there assailed by a myriad of leeches ("litteralmente assalito da una miriade di sanguisughe"). On being rescued and removed to the hotel he died on the third day from the loss of blood in an enfeebled constitution.

In vol. xxiv., p. 539, of the *Edinburgh Medical Journal* there is a notice of a communication in Italian sent to me by Professor Sotà y Lastra of Seville, entitled "*Una Mignatta estratta dalla Laringe quindici giorni dopo che vi era penetrata*" ("A Leech extracted from the Larynx fifteen days after it had entered therein"). It states that on Aug. 3rd a man aged sixty four, tall and robust, presented himself at the Polyclinic of Seville complaining of blood freely issuing from his mouth for fifteen days past. At the beginning of that period, being thirsty, he had drunk copiously of cold water from a ditch and immediately after felt constriction in the throat, respiration becoming impeded and voice extinct. After this he was obliged to cough continuously owing to tickling in the larynx. Several hours afterwards blood commenced to issue from the mouth, a little at first, but abundantly later on. He was able to swallow solids and fluids easily. He slept badly, accessions of suffocation awakening him continually. In a few days he became visibly thinner, losing strength and colour. On examination Dr. Sotà found the temperature normal, pulse rapid and weak, respiration painfully strident and quickened; thorax dilated fully, vocal vibration normal, as also percussion and auscultation, though the latter was impeded by the laryngeal stridor. Having introduced the laryngoscopic speculum he discovered a leech fastened to a reddish elevation of the epiglottis immediately above the anterior commissure of the cords, extending upwards and backwards, while the caudal extremity was fixed in the right arytenoid. After five attempts necessitated by the restlessness of the patient, Professor Sotà succeeded in extracting the annelide. This was followed by an immediate and complete recovery.

From the same author I have just now received a history of a case ("*Sanguignuel adherida al nivel del Cuarto Anillo de la Traquea*")—"A Leech attached to the Fourth Ring of the Trachea"—originating in a similar subject from the same cause. But here there was neither dysphonia nor dysphagia, and after many efforts Professor Sotà observed vermicular movements in a dark mass like coagulated blood at the anterior and middle portion of the trachea. By means of a ball of cotton moistened with a solution of chlorhydrate of cocaine of 10 per 100 applied to the locality and thereby anaesthetised he managed by the laryngeal forceps to extract a small leech 22 millimetres in length and 3 in breadth after difficulties in the achievement that seemed almost insuperable. As an offset to these instances of pernicious local depletion I may refer to one of a contrary character in the case of the poet-statesman, M. de Lamartine, who in his "*Pictures of the East*," relates that when resting at Yenikeni, a village in South Bulgaria, he was seized with "*fièvre et une inflammation du sangue*," probably pneu-

monia, which confined him for twenty days, at first without medical aid. But Madame de Lamartine was equal to the emergency. She sent out the Bulgarians to the marshes in the plain to look for leeches, which they discovered. Sixty of these annelides, applied to the chest and the temples, diminished the danger. The patient recovered consciousness on the sixth day of the fever. The danger already passed over, his friends at Adrianople having heard of his malady came to visit him with all sorts of remedies, leaving him in charge of a young Macedonian physician (educated at Semlin in Hungary) who spoke Latin, but his talents were unnecessary, the affectionate presence of mind and energetic resolution of the lady having supplied all that was required, the doctor's pleasant society being all that aided to complete the cure. While gratified by the immense advance in pathology since the date of the foregoing history, it may be questioned if there has been a corresponding progress in therapeutics all along the line—indeed, if there may not have been a retrogression in one important particular I allude to the almost total disuse of topical as well as general depletion in modern practice. We have been so concerned with the microscopic investigation of the blood plasma, the number and behaviour of the red and white corpuscles, that we have undervalued to a great extent the importance of the macroscopic indications of dolor, tumor, calor, rubor. Yet in most cases of inflammation near the surface there they are and, unlike the hero's spouse, may not be explained away.

The pulmonic circulation was first clearly described in his "Restitutio Christianismi" in 1553 by the irreproachable, ill-starred genius Migue! Serreto y Revés de Villanova, and if he had not then been judiciously murdered by Calvin at Geneva he most undoubtedly would have completely anticipated Harvey by a full century. From a pathological point of view the minor or pulmonic may be esteemed paramount to the general circulation. The blood is duly oxygenated in the capillaries of the air cells, but it is imbued with more than oxygen. Every inspiration imbibes whatever may be floating in the aerial ocean in which we move—sulphuretted hydrogen, carbonic oxides, the microbes and germs that are present in the aerial strata with which we are brought in contact—all these are sent into the left heart cavities, irritating the endothelium and being propelled on to the remotest capillaries. In the vast agglomerations of human beings now concentrated in cities every item of which helps to poison his or her neighbours, and the morbid results show clearly of how much greater sanitary consequence is what we breathe than what we eat or drink, apart from specific contagion in our water or dietary.

The arterial blood, thus contaminated in its progress through the capillaries when meeting with local lesions, cellular or vascular local degenerations, accumulates and stays. Considering that our system is so much made up of vascular network the derangements from local congestion and stasis are easily explicable and the obvious relief from capillary drainage from leeching or cupping is as comprehensible. It appears to me that we have laid too much stress on the nervous system in our endeavours to relieve the suffering arising from inflammatory lesions and overlooked the soothing influence of unloading the affected tissues. Take, for example, the case of perityphlitis—a malady sufficiently tangible and in which it might be reasonably expected that the cutaneous circulation would be quite accessible for the relief of the congestion around the ileo-cæcal valve and appendix. In a modern book of reference we find rest, poultices and fomentations enjoined in the treatment of this disease. I have seen instances of such treatment followed by lingering distress, ending in death at the end of the second month, even though opium had been largely given. This drug to many seems to be the catholon for most abdominal maladies. Very different was the issue when leeches had been freely and vigorously applied. Among our junior brethren there appears to prevail a vague fear of the depressing enfeebling effect of local depletion. A leech may extract from a drachm to even three drachms of blood itself and the fomentations or poultices subsequently fully as much more, but when we take into account the entire mass of blood in the average human body we readily perceive the futility of this objection. In Hermann's 'Grundriss der Physiologie des Menschen' (Blutmenge) Bischoff's estimate is one-thirteenth of the weight of the body. Welcker gives it at one-nineteenth in the newly born. The derivation of all abstracted by an ordinary application of these annelides need not give rise to any serious apprehension on this score. Pain is the most debilitating of all influences, and where pain is there is effusion. To diminish the latter is in the

great majority of cases the best means of abolishing the former, hence the wisdom of the frequent injunction of our predecessors—"Put on so many leeches on the sore part."

Gowanlee Slamannan, N.B.

ON MIGRAINE

BY ALEXANDER WALLACE, M.D. OXON &c.,
PHYSICIAN TO THE ESSEX AND COLCHESTER HOSPITAL.

I SUPPOSE that after a personal experience of over ^{sixty} years of this unsocial malady I might, perhaps better than others, have somewhat of use to say concerning it. I call it an "unsocial malady," because it often cruelly debars the sufferer from moving in society and enjoying family and friendly intercourse. I will relate my own experiences. My diathesis is gouty, though I have never had an acute attack, I have nodules in my ears and have often been troubled with eczema and pharyngeal irritation.

Personal experiences—Migraine with me began early in life, I well remember when at school not infrequently experiencing severe headache followed by vomiting—one instance will never be forgotten. When about ten or eleven years old, one Saturday afternoon, I was unusually lucky at cricket, scoring over 100 runs off my own bat and coming back correspondingly hungry and tired. The next day I woke with a headache and, dimly forecasting the result, petitioned to be let off "church." "No, I must go," was the edict, so during the Litany, feeling bad, I sought my hat (in those days we always went to church in tall hats). Some delay arose in getting me one (not my own), so before I could get out vomiting took place, and out of respect to the sacred edifice I used the hat for a receptacle. How I got back, miserable, I forget, but next day I got a thrashing from the boy whose hat I had thus defiled, and at the end of the term a new hat was debited to my school account. Another sad experience, later in life, I may record. In my early professional career I was invited for the first (and only) time to the dinner table of a distinguished judge. I had dined out the day before with a relative and in consequence woke in the morning with a slight headache, I nursed myself all day, hoping to recover, but in vain. I had hardly got through my soup, sitting at my hostess's right hand, when the usual result followed and I had to beat a precipitate and ignominious retreat. Taught by bitter experience, many and many a pleasant social evening have I relinquished knowing well how dangerous it was for me to go. In my case migraine has certainly been a miserably unsocial and painful drawback. These attacks continued more or less frequently during my youth and during a ten years' residence in London, often prostrating me at a time when I wished to be at work or to be at my best in society. After settling in Colchester, thirty years ago, they at first remitted somewhat, but soon got so frequent as to come on regularly every Saturday. I then consulted the late Dr. Brinton, who advised me to try Aix la Chapelle or the top of a Welsh mountain. I went, however, to Harrogate and after a three weeks' sojourn came home in renewed health, though I was told that on my arrival at the hotel the other visitors pronounced me to be a promising candidate for the cemetery. For the next ten years I paid an annual visit to Harrogate, conforming to the customs of the place and deriving great benefit therefrom, until at length I learnt from my Harrogate experiences how to mitigate the virulence of my attacks and at last how to obviate them almost altogether. Now, though I go elsewhere for my holiday, I rarely suffer from an attack, but, in order to attain this end I have to forego many social enjoyable evenings.

Description of an attack.—In my case the advent of a migraine is generally recognised on awaking by a desire to lie still and avoid all mental and bodily exertion, the head is hot, feels heavy and dull, if not already aching the eyes lack lustre, the tongue is slightly coated, there is anorexia and some thirst, the urine is frequently pale and of light specific gravity. During the day the necessary work is done with much effort, fatigue and irritability of temper, the headache increases and about 4 or 6 P.M. compels me to lie down and cease from all further effort, later on the headache becomes more intense and throbbing and culminates in a copious acid vomit, after which relief and sleep come, and in the morning I arise free from headache but with a tired strained feeling and some muscular soreness. The temperature during the attack is

abnormal but rises after the vomiting, with free skin action and discharge of orange-coloured lithates in the urine, the contents of the stomach seem to be retained for hours and get rid of only by vomit.

Relief—Now the lessons learnt from many attacks have taught me that a severe bout of migraine is relieved most certainly and completely by the concussion of vomiting, the stomach being thus emptied of its contents, circulation and absorption being restored. I have cut short (when absolutely necessary) the attack by an early hypodermic injection of apomorphia, but the remedy with the attendant depression and vomiting is as bad as the disease.

Treatment of an attack—The severity of the headache is in my experience directly proportionate to the amount of the acidity of the gastric contents and it can be greatly lessened by the free imbibition of alkaline draughts—salty volatile, soda, ginger and peppermint with spirit of chloroform in a tumbler of cold water being with me a favourite and very effective drink. Two or three tumblers of this will almost certainly relieve the headache. Solid food is undesirable and rarely taken. Abstinence except from drink is the rule during the day. When vomiting is over, the exhibition of an alkaline drink such as I have mentioned is very agreeable to neutralise the stomach acidity, and then a few grains of blue pill, compound colocynth and extract of hyoseyamus will induce sleep and act like a charm.

Alkaline drinks—The exhibition of alkaline drinks may be pushed further, and if used earlier in the day may relieve entirely the headache and prevent vomiting. I see in my out-patient room many cases of migraine, some severe ones, and I have often found that copious draughts of water during the day or night, a tumblerful at a time taken frequently up to two or three quarts in amount, prove very useful in mitigating the headache and aborting the attack. The rationale of its action seems to be that it dilutes, neutralises, and washes onwards the acid contents of the stomach, promoting intestinal action.

Prevention—As prevention is better than cure, I am now able after years of suffering to detect the early symptoms of a coming attack, and to commence treatment twelve or twenty-four hours in advance, so as to abort the migraine altogether. (See end of paper.) I have been able also to trace in myself the numerous faults either of habit or environment which produce migrainous headache, and so, recognising the exciting causes, have been able so to adapt my mode of life as now to escape almost altogether the dreaded evil.

Exciting causes—First, then, in my case and in many others which I have treated I lay down the proposition that a migraine is due to defective or insufficient excretion, partly of the liver but mainly of the kidney. Migrainous patients will present a muddy, sallow complexion, a dull eye, yellowish conjunctivæ and a yellowish tint of skin. On inquiry you learn that the bowels are constive, not acting daily, that though the urine after an attack is high in colour and loaded with lithates yet before and during the attack it is pale and limpid and, if you examine it, of low specific gravity. You will find that just before the attack your patients are inert and lazy, probably complain of backache and are indisposed to mental and bodily exertion, they will tell you that after the attack they are more cheerful and bright, can enjoy their food and social intercourse and feel brisk for work, whereas just before the attack they are unduly irritable, short-tempered and nothing goes right with them. You will probably also on close inquiry get at a history of stultence and cruciation suggestive of liver congestion. All these little matters are to me now well recognised symptoms of the coming storm yet for a long time they passed unnoticed, but thus forewarned I am able, as I shall show later on, either to minimise the evil or avert it altogether. Now, regarding migraine as produced by defective or insufficient excretion, chiefly of the kidney, two quite opposite conditions may be at work to excite an attack. (1) Where the abdominal and eliminative organs are less able than usual to perform their work and (2) where a greater onus is thrown on these organs than they can for the time being perform. Under Cause 1 may be classed check of skin action, exposure to cold, heated and vitiated atmospheres, tobacco (in some), alcohol, malt liquors, drugs, tea and other articles of food which act as economisers, lessening excretion, an insufficient imbibition of fluid, fatigue, nervous prostration &c. I have frequently noticed in my own case that after exposure to cold the urine is of light colour and of low specific gravity, and that a slight headache has supervened. Alcohol and malt liquors I have been unable to take for years, except in very small quantities, and that only occasionally. Any

indulgence in this respect is invariably followed by headache. Tea is notoriously avoided by sufferers from migraine. I have noticed that in the month of November, when the atmosphere is loaded with damp, is anticyclonic and more or less impure from fog and smoke, with a low barometer, migraines are unusually prevalent.

It is hardly necessary to point out here that a scanty daily imbibition of fluid leads to insufficient intestinal and kidney action, inducing constipation and generally defective secretion and excretion, and is a common cause of anæmia. The converse of this is beautifully shown by the treatment carried out at Harrogate and similar Spas, where under the influence of water containing more or less sulphate of soda, sulphate of magnesium and chloride of sodium, exhibited externally by baths and internally by drinks, free excretion is promoted. The skin becomes clear and rosy, the evacuations are loose and free, the temper changes from irritable to joyous and the patient returns home rejuvenated.

Under Cause 2 may be mentioned over exertion of body or mind, over eating (a common cause), indulgence in saccharine and fatty foods, specially in jams, rich soups and stews, pastry and the like, interference with the digestive powers (which are generally weak) by irregular or too prolonged meals (our present dinners now often last three hours) or indigestible food, such as pork, salt meats &c., insufficient mastication, mental or bodily exercise immediately following a principal meal, costiveness or constipation &c. These and similar causes interfering with the proper assimilation and excretion will in the case of sufferers from migraine prove exciting causes of an attack. It follows therefore that an individual so disposed should modify his environment and faulty habits (if any), and should lay down, and confine himself within, certain limits beyond which he dare not pass without risking an attack.

Prevention—Prevention of migraine is the result of a due and well balanced performance of assimilation and excretion, to maintain which a proper healthy exercise of mind and body, a careful dietary, regular hours and due intestinal and kidney excretion are necessary. To go more into detail. "In the sweat of the brow shall the bread be eaten" is very true of the sufferer from migraine. Enervating till perspiration ensues followed by a bath or good rub down and a change of dry clothing, promotes a healthy appetite and improves digestion. Great attention to this was paid by the Romans in the time of their emperors, and nowadays the social game of lawn tennis supplies an admirable and pleasant exercise without undue fatigue. Then as regards excretion. It is said that when the mountain did not go to Mahomet he went to the mountain. If we cannot go to Harrogate or Aix la Chapelle, a tumbler or two of hot water while dressing in the morning containing sufficient mineral salts (including chloride of sodium) to produce a free loose stool after breakfast will help kidney action and not interfere with the digestion. Different aperient waters suit different individuals. I mention chloride of sodium advisedly as a necessary constituent because it induces thirst and thus paves the way to copious daily drinks, so that from three to four pints of fluid may be taken pleasantly during the day. I have tried Turkish baths, but they did not suit me and are far less pleasant than lawn tennis, though to some they are very useful. As to diet, plenty of fresh food, fresh fruit, fresh vegetables, fresh butter, fresh meat (in moderation) and milk are desirable, no twice cooked dishes, no salted or pickled food, no jam tarts or treacle. In other words, while promoting excretion care must be taken to supply easily assimilable material. Above all eat sparingly and rise from the table still hungry rather than eat to repletion, a difficult habit for the young to cultivate.

To abort an attack—If an attack be apprehended—and attacks will threaten from time to time—provided the warnings are recognised the day before, treatment should be at once commenced. The dietary should be spare, light and contain much fluid, nothing should be taken after 7 P.M. except a drink of milk and soda water and a biscuit, the before mentioned pill should be taken at bedtime and an alkaline draught in the morning while dressing, with the addition of iodide of potassium or salicylate of soda in a tumblerful of hot water. This will in all probability avert the attack. Migraines in the female are of a less robust character than in the male sex, as might be supposed from their different habits and environment, their generally anæmic condition and proneness to reflex excitation, but the exciting causes underlying an attack are much the same and may generally be detected. Scanty drinking and abuse of the temper are frequent causes, while

nausea and constipation claim many victims. Migraines are generally more prevalent among women than among men, and slight attacks which are very common, of an irritable tendency to interfere or trouble of patients.

I trust that these remarks may help my fellow sufferers to escape from the fetters of this dreadful malady.

S. J. HARRISON, O'Connell.

SEVERE OCCIPITAL HEADACHE SUBCUTANEOUS INJECTION OF MORPHINE RECOVERY.

By WILLIAM H. DAY, M.D. M.R.C.P. LOND.

CONSULTING PHYSICIAN TO THE SICKENESS HOSPITAL FOR WOMEN AND CHILDREN.

ONE of the most severe cases of occipital headache of a very strange nature that I have ever seen came under my notice in May 1892. A married lady sixty-two years of age and the mother of six children, was much distressed in health from anxiety and care. She had been for twenty-five years a sufferer from nervous headache, treated in a great measure to anemia from excess of the treatment in early married life and to numerous attacks of menorrhagia. Until the summer of 1891 the pain of the commencement of an attack had generally been frontal, extending to the vertex accompanied with great nausea, vomiting and loss of food. After a period of rest and education the frontal pain very gradually followed by severe neuralgia in the course of the fifth nerve especially the supraorbital and supra-temple branches on one or the other side. The symptoms then branched into the nerves affected as is often the case. Occasionally the ophthalmic nerve with its branches to the nasal gland and eye was specially affected when the ophthalmic branch was cut and the eye would run down the cheek. On other occasions the nasal nerve would be involved, and a strong pain would extend down one side of the nose. Sometimes pain in the temporal and occipital branches of the supra-temple nerve were involved the pain would be very severe, often filling half of the temporal front, owing to transference of sensation from communication with the deep temporal nerve. On other occasions the parietal nerve swinging from the supra-temple would be affected, and then the patient knew that headache was impending from a peculiar sensation on one side of the temple and a free flow of saliva. Sometimes she was able to promenade on a cushion from a couch a distance of twenty miles. Six months previous to the occipital seizure the patient should have had a hysterectomy, she was confined on occasion, she grew pale and weak, and on walking upstairs experienced some breathlessness, although she had no heart and lungs were sound. The attack began at 3 A.M. on May 10th 1892 with a feeling of weight on the top of the head. Soon the patient could not remain in bed, although she was at a time when she would place her arm and hand pressure on the vertex of the crown. She remained in bed at frequent intervals, coming up to the window for air. The pain gradually increased in severity and the patient was exhausted and restless from continuing to sleep on the following day (the 11th) at 2 P.M. a quarter of a grain of morphine was injected into the left occipital nerve. In a minute she was easy and in five minutes fell into a quiet sleep, when continued on and off for several nights. On the 15th occipital headache came on again and after using for forty-eight hours the relief was obtained by taking five-grain doses of quinine with ten minims of spirit of chloroform every four hours. Doses and expectorant were taken freely. On the 18th there was more pain and the patient was worn out from suffering and sleeplessness. The pulse was weak, the pulse was weak and when the eyes were wide awake and under the head the face was deadly white and the angles of the mouth were drawn down, giving the patient a most worn and distressed expression. Quinine in doses of five grains, rectified chloroform, spirit of chloroform and eggs (a diet) than formerly and a remedy relieved the (first seizure) now failed to

afford any relief. Bromides neither produced sleep nor allayed the pain. As the patient was going from bed to worse and as sleep was essential after four nights and days of acute suffering, it was decided to again have recourse to the hypodermic injection of morphine (gr. 1/2). This was carried out as before and in half a minute was followed by cessation of pain and tranquil sleep, at intervals for the ensuing twenty-four hours. When the pain was at its height before the morphine was used, firm pressure with the open hand over the seat of pain afforded some relief and a lot of warm sea also mitigated it. A mustard emulsion to the neck, or a stimulating liniment of chloroform and alcohol gave temporary relief when the pain was not very acute. The pain was mainly referred to the course of the great occipital nerve where it crosses the trapezius muscle and over its cranial distribution as far as the vertex. Sometimes pain was also experienced over the upper and posterior aspect of the ear. In addition to the symptoms described, after the occipital pain was relieved, the patient experienced a painful sensation in the movement of the lower and upper part of the neck. So numerous are the manifestations and extension of the occipital nerve with its branches of other nerves especially the trigeminal and ascending branches of the cervical plexus, in this situation that they do not explain how the pain may extend from the crown down to the mouth, teeth and lower jaw. No treatment was available to cure this, every stump having been removed for years before the seizure and morphine made good by artificial means. On the 20th the patient passed a restless and wakeful night, complaining of pain in the back of the head, but after taking the powerful nature of accurate and applying a stimulating liniment to the neck the sleep at intervals. On the 22nd it was removed, she had passed a better night and the pain was of a sage or character, but not extended to the cervical nerves, making it rather difficult to turn the head and open the mouth freely. She took food well. On the following day the pain had extended down the neck, arm and the attempt to lift anything with the right hand, which was very weak, immediately brought on a return of the pain. She also complained of stiffness of the neck, back of the wrist. As soon as the pain was due to come with the next to a quiet country place in a pure atmosphere and had two months of complete rest, seldom getting up till midday and returning to bed at an early hour. On returning to town the next morning water in the "cold" form only after lunch and has continued doing so up to the present time. There has been no return of acute pain since, and the patient is now healthier than she has been for the last two years.

Remarks.—The effect of the subcutaneous injection of morphine in this case, as in many similar cases, is to tranquillise the patient at once and speedily to relieve the pain, all other remedies had failed one after another. On no and on many other previous occasions they proved utterly worthless. This mode of applying morphine removes the true and nature of the pain, brings it into the surface and removes the excessive excitation and collapse which are manifestly present after the seizure has continued many days. When the effect of the morphine has passed off the system is almost nervous and the quantity of stimulant which would be certain to induce a headache, now keeps it away. When morphine is employed for the first time subcutaneously a small dose should be given, as some persons are peculiarly affected by it. It sometimes induces very serious symptoms but I have not observed any in my own experience. Such cases are, however, recorded from time to time. Dr. Smith of Capetown, Cape of Good Hope, sent to me a married lady thirty-nine years of age in August 1892 suffering from severe neuralgic headache. He and other medical men and tried many remedies without avail and amongst them the hypodermic injection of morphine and chloroform, which caused frightful effects and other alarming symptoms without bringing relief. From the many disastrous consequences that have followed, as they certainly will follow, the repeated use of morphine subcutaneously employed we cannot be too cautious in very much resorting to it. It is only in such a severe case of headache as I have related, when pain and sleeplessness are wearing out the patient that its use is justified. When employed with care and at long intervals, it is not likely to cause clinically or physically the abnormal structure of the body and nervous system, but if resorted to at every severe paroxysm of headache or whenever the patient clamors for it, he will be gradually brought into a possible state of mind and body.

On some previous occasions in severe attacks of occipital headache I have found that a grain of quinine with ten minims of rectified chloroform and eggs (a diet) than formerly and a remedy relieved the (first seizure) now failed to

subnormal but rises after the vomiting, with free skin action and discharge of orange-coloured lithates in the urine, the contents of the stomach seem to be retained for hours and get rid of only by vomit.

Relief—Now the lessons learnt from many attacks have taught me that a severe bout of migraine is relieved most certainly and completely by the concussion of vomiting, the stomach being thus emptied of its contents, circulation and absorption being restored. I have cut short (when absolutely necessary) the attack by an early hypodermic injection of apomorphia, but the remedy with the attendant depression and vomiting is as bad as the disease.

Treatment of an attack—The severity of the headache is in my experience directly proportionate to the amount of the acidity of the gastric contents and it can be greatly lessened by the free imbibition of alkaline draughts—sal volatile, soda, ginger and peppermint with spirit of chloroform in a tumbler of cold water being with me a favourite and very effective drink. Two or three tumblers of this will almost certainly relieve the headache. Solid food is undesirable and rarely taken. Abstinence except from drink is the rule during the day. When vomiting is over, the exhibition of an alkaline drink such as I have mentioned is very agreeable to neutralise the stomach acidity, and then a few grains of blue pill, compound colocyth and extract of hyoseyamus will induce sleep and not like a charm.

Alkaline drinks—The exhibition of alkaline drinks may be pushed further, and if used earlier in the day may relieve entirely the headache and prevent vomiting. I see in my out-patient room many cases of migraine, some severe ones, and I have often found that copious draughts of water during the day or night, a tumblerful at a time taken frequently up to two or three quarts in amount, prove very useful in mitigating the headache and aborting the attack. The rationale of its action seems to be that it dilutes, neutralises and washes onwards the acid contents of the stomach, promoting intestinal action.

Prevention—As prevention is better than cure, I am now able after years of suffering to detect the early symptoms of a coming attack, and to commence treatment twelve or twenty-four hours in advance, so as to abort the migraine altogether. (See end of paper.) I have been able also to trace in myself the numerous faults either of habit or environment which produce migrainous headache, and so, recognising the exciting causes, have been able so to adapt my mode of life as now to escape almost altogether the dreaded evil.

Exciting causes—First, then, in my case and in many others which I have treated I lay down the proposition that a migraine is due to defective or insufficient excretion, partly of the liver but mainly of the kidney.

Migrainous patients will present a muddy sallow complexion, a dull eye, yellowish conjunctivæ and a yellowish tint of skin. On inquiry you learn that the bowels are constive, not acting daily, that though the urine after an attack is high in colour and loaded with lithates yet before and during the attack it is pale and limpid and, if you examine it, of low specific gravity. You will find that just before the attack your patients are inert and lazy, probably complain of backache and are indisposed to mental and bodily exertion, they will tell you that after the attack they are more cheerful and bright, can enjoy their food and social intercourse and feel brisk for work, whereas just before the attack they are unduly irritable, short-tempered and nothing goes right with them. You will probably also on close inquiry get at a history of stultence and eructation suggestive of liver congestion. All these little matters are to me now well recognised symptoms of the coming storm yet for a long time they passed unnoticed, but thus forewarned I am able, as I shall show later on, either to minimise the evil or avert it altogether. Now, regarding migraine as produced by defective or insufficient excretion, chiefly of the kidney, two quite opposite conditions may be at work to excite an attack. (1) Where the abdominal and eliminating organs are less able than usual to perform their work and (2) where a greater onus is thrown on these organs than they can for the time being perform. Under Cause 1 may be classed check of skin action, exposure to cold, heated and vitiated atmospheres, tobacco (in some), alcohol, malt liquors, drugs, tea and other articles of food which act as economisers, lessening excretion, an insufficient imbibition of fluid, fatigue, nervous prostration &c. I have frequently noticed in my own case that after exposure to cold the urine is of light colour and of low specific gravity, and that a slight headache has supervened. Alcohol and malt liquors I have been unable to take for years, except in very small quantities and that only occasionally. Any

indulgence in this respect is invariably followed by headache. Tea is notoriously avoided by sufferers from migraine. I have noticed that in the month of November, when the atmosphere is loaded with damp, is anticyclonic and more or less impure from fog and smoke, with a low barometer, migraines are unusually prevalent.

It is hardly necessary to point out here that a scanty daily imbibition of fluid leads to insufficient intestinal and kidney action, inducing constipation and generally defective secretion and excretion, and is a common cause of anemia. The converse of this is beautifully shown by the treatment carried out at Harrogate and similar Spas, where under the influence of water containing more or less sulphate of soda, sulphate of magnesium and chloride of sodium, exhibited externally by baths and internally by drinks, free excretion is promoted. The skin becomes clear and rosy, the evacuations are loose and free, the temper changes from irritable to joyous and the patient returns home rejuvenated.

Under Cause 2 may be mentioned over-exertion of body or mind, over eating (a common cause), indulgence in saccharine and fatty foods, specially in jams, rich soups and stews, pastry and the like, interference with the digestive powers (which are generally weak) by irregular or too prolonged meals (our present dinners now often last three hours) or indigestible food, such as pork, salt meats &c., insufficient mastication, mental or bodily exercise immediately following a principal meal, costiveness or constipation &c. These and similar causes interfering with the proper assimilation and excretion will in the case of sufferers from migraine prove exciting causes of an attack. It follows therefore that an individual so disposed should modify his environment and faulty habits (if any), and should lay down, and confine himself within, certain limits beyond which he dare not pass without risking an attack.

Prevention—Prevention of migraine is the result of a due and well balanced performance of assimilation and excretion, to maintain which a proper healthy exercise of mind and body, a careful dietary, regular hours and due intestinal and kidney excretion are necessary. To go more into detail "In the sweat of the brow shall the bread be eaten" is very true of the sufferer from migraine. Energising till perspiration ensues, followed by a bath or good rub down and a change of dry clothing promotes a healthy appetite and improves digestion. Great attention to this was paid by the Romans in the time of their emperors, and nowadays the social game of lawn tennis supplies an admirable and pleasant exercise without undue fatigue. Then as regards excretion. It is said that when the mountain did not go to Mahomet he went to the mountain. If we cannot go to Harrogate or Aix la Chapelle, a tumbler or two of hot water while dressing in the morning containing sufficient mineral salts (including chloride of sodium) to produce a free loose stool after breakfast will help kidney action and not interfere with the digestion. Different aperient waters suit different individuals. I mention chloride of sodium advisedly as a necessary constituent because it induces thirst and thus paves the way to copious daily drinks, so that from three to four pints of fluid may be taken pleasantly during the day. I have tried Turkish baths, but they did not suit me and are far less pleasant than lawn tennis, though to some they are very useful. As to diet, plenty of fresh food, fresh fruit, fresh vegetables, fresh butter, fresh meat (in moderation) and milk are desirable, no twice cooked dishes, no salted or pickled food, no jam tarts or treacle. In other words, while promoting excretion care must be taken to supply easily assimilable material. Above all eat sparingly and rise from the table still hungry rather than eat to repletion, a difficult habit for the young to cultivate.

To abort an attack—If an attack be apprehended—and attacks will threaten from time to time—provided the warnings are recognised the day before, treatment should be at once commenced. The dietary should be spare, light and contain much fluid, nothing should be taken after 7 P.M. except a drink of milk and soda water and a biscuit, the before-mentioned pill should be taken at bedtime and an alkaline draught in the morning while dressing, with the addition of iodide of potassium or salicylate of soda in a tumblerful of hot water. This will in all probability avert the attack. Migraines in the female are of a less robust character than in the male sex, as might be supposed from their different habits and environment, their generally anemic condition and proneness to reflex excitation, but the exciting causes underlying an attack are much the same and may generally be detected. Scanty drinking and abuse of the temper are frequent causes, while

soon, had no sickness to speak of and made a rapid and excellent recovery. The history of this case, taken with the matted condition of the intestines and the adhesion of the tubes to them and to the pelvic organs, distinctly points to the attack of abdominal inflammation as the starting point of the tubal disease. I quite expected to find the contents of both tubes offensive, but on opening them after removal the pus that escaped was creamy and not in the least degree fetid. It is somewhat remarkable that a woman with two such tumours should have enjoyed good health and have been able to ride and drive up to the time of her operation without any ill effects. Had the tubes burst during such violent exercise the result would have been disastrous, if not actually fatal, within a few hours.

This is the third consecutive case in which I have succeeded in removing adherent and distended tubes unruptured, and during the last ten years I have had many opportunities of assisting at operations for the removal of diseased and dilated tubes. It is the practice of some surgeons to aspirate or use a small trocar in such cases, and when they have emptied the tubes they then proceed to remove them. Speaking from

FIG 2.

A distended Fallopian tube, doubled upon itself

my own experience I prefer, if possible, to remove the tubes unemptied and unruptured, for once the contents are with drawn it seems to me that the operator loses his landmarks and the difficulties of the operation are increased tenfold. In the cases where I have seen intestines torn or pelvic organs injured I have noticed that the injury invariably occurred subsequently to the emptying or rupturing of the dilated tube. When operating on such like cases I endeavour to use the pulp of my fingers as much as possible, working them as one would a sponge when dealing with intestinal adhesions, and thus keeping the finger nails away from the tubes. This method is of course tedious and cannot be carried out in every case, but it is undoubtedly safe and in my opinion worthy of a trial. I am convinced that irremediable injury may be inflicted on the intestines and on the pelvic organs by injudicious scraping and by digging with the finger nails into the depths of the pelvis where the parts are completely hidden from sight.

I have much pleasure in acknowledging the valuable assistance rendered by Drs Copeland and Fawson Lee during

the operation. My thanks are also due to my friend Mr Stormont Murray for his skilful administration of the anæsthetic and to Mr J Bland Sutton, who very kindly undertook to examine and report on the specimens, which were exhibited at the February meeting of the Obstetrical Society. His report is as follows: "The cysts are enormously distended Fallopian tubes. Sections prepared from them exhibit a thin layer of muscle tissue lined internally with granulation tissue. There are no traces of epithelium and the mucous membrane has completely disappeared. Large dilated tubes of this character differ in many points from the common forms of pyosalpinx secondary to septic endometritis and gonorrhœa. I have only seen two other examples similar to these specimens, and until more is known of their pathology they should stand in a separate class." The illustrations were executed by Mr Henry R. W. Lewin.

N.B.—Dr Fawson Lee informs me by letter dated October, 1892, that the patient is now quite strong and well. She has gained flesh and is in excellent spirits. There has been no complaint of dyspareunia since the operation. A regular catamenial period occurred in March and has recurred about every month, much the same in quantity, but varying somewhat as to time and unattended by any pain.

ST THOMAS'S HOSPITAL.

NOTES OF A FATAL CASE OF STRYCHNINE POISONING, REMARKS

(Under the care of Dr JOHN HARLEY.)

FATAL cases of poisoning by strychnine in which the patient lives long enough for the symptoms and course of events to be carefully noted being of rare occurrence, the following notes taken by Dr Cuthbert Wyman, formerly house physician to St. Thomas's Hospital, to whom we are indebted for them, will be found of interest. We commented in THE LANCET some months ago¹ on the fact that strychnine had been used somewhat frequently during the last few years for the purposes both of suicide and homicide, and pointed out the ease with which the poison could be obtained in various compounds and the danger which this was to the public health. There was another aspect we dwelt upon and which we considered of importance—that was the possibility of mistaking the symptoms for those produced by 'natural causes.' While the symptoms of strychnine poisoning are well known they vary very much according to surrounding circumstances. When the dose has been large the tetanic spasms will be well marked, but when a minimum fatal dose has been given these will be modified into a species of convulsions which may be regarded as unconnected with poison. Hence the importance of not only observing the symptoms of any sudden attack of convulsions very carefully, but also of duly weighing all the surrounding circumstances, the previous taking of food or medicine, the absence of any former similar attack and the appearance and manner of those around. It is curious that the rapidity with which the symptoms of poisoning developed in these cases varied so much. The patients were young women of about the same age, and the contents of the stomach in each and the amount of poison taken were presumably similar, yet one died almost immediately and the other lived for about five hours and a half. In 1889 we published notes of a case under the care of Mr H. C. W. Jones,² where recovery followed treatment for strychnine poison, the quantity swallowed being estimated at

¹ THE LANCET, vol. i. 1892, p. 1376.

² *Ibid.*, vol. i. 1889, p. 168.

The severe nervous and neuralgic types of headache in the case in question were in a great measure owing to excess of the catamenia and attacks of menorrhagia from time to time in earlier years, by which the blood became impoverished and the general tone of the nervous system lowered. The mother and sister of the patient furnish a similar history. It seems reasonable to suppose that this state of things frequently lays the foundation of severe neuralgia, which does not happen in middle life when there is still resistance left, but comes on gradually with increasing years and declining strength. Clinical evidence, as in this case at least, supports the theory. Then if there is a frequent repetition of the attacks the muscles and nerves give way under slight provocation, the heart palpitates and becomes irregular in its action and that which at first was a purely neurotic condition may eventually merge into organic mischief. The nervous failure has invited it. As soon as the pain was relieved in this case we had to deal with an anæmic condition in which the blood was deficient in one or more of its constituents. So long as this continues a general state of debility is established leading to malnutrition and sometimes to chronic disease. The subjects of this form of headache, fearing a recurrence of the attacks of pain, are often afraid to take the necessary nourishment to support the system and they too frequently live under conditions not conducive to health in matters of air and exercise. To cure an anæmic tendency and to remove it when established are the best means of warding off recurring attacks of neuralgic headache. I have had many opportunities of observing the good effects of Levico water ("mild") in these cases. It has when continued long enough imparted colour to the cheeks and removed some of the uneasy sensations, as breathlessness, palpitation &c, when the blood is deficient in hæmoglobin. Differences of opinion have arisen as to whether the iron administered is actually absorbed. It seems to me that it is. Hamburger and others consider that very little is absorbed from the abdominal canal. The quantity of iron, says Dr Halliburton, in the whole body is only three grammes, and this quantity is taken many times over during treatment.²

A RARE FORM OF DOUBLE PYOSALPINX

By A C BUTLER SMYTHE, F.R.C.S. EDIN.,

SURGEON TO OUT PATIENTS SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN AND SURGEON TO THE GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN

In December 1891 I was asked by Dr Cullingworth, who was ill at that time, to see and if necessary to operate on a young lady who had an abdominal tumour. The patient aged twenty six, had been married five years, but had never become pregnant. Ever since marriage coitus had been painful, but latterly the pain was very severe. Seven years ago she was laid up with pleurisy and was tapped on the right side. Six months later she had an attack of abdominal inflammation and kept her bed for some weeks, during which time her abdomen was much swollen, the circumference below the umbilicus measuring thirty two inches. As she recovered from the attack the swelling subsided and her figure resumed its normal shape. A few months later she married, and during the subsequent five years enjoyed very fair health. In October, 1891, she complained of pain in the lower part of the abdomen and thought she could feel a swelling there. Dr Fawson Lee of Salisbury was consulted, and he, recognising the gravity of the case sent her to London for further advice. She was taken to a house in Harley-street, where I saw her in consultation with Dr Lawrence Copeland the day after her arrival. On examination a large elongated swelling, centrally situated and reaching to the umbilicus, was detected. It was freely movable from side to side, but was not tender to touch. The uterus was pushed up in front of the tumour and could be distinctly felt through the abdominal walls. Bimanually the lower part of the tumour was found to occupy Douglas's pouch, from which it could not be dislodged. On the left side of the uterus was there another large fixed swelling which filled the pelvis on that side. The sound passed into the uterus two inches and a half but that organ could not be separated from the two swellings. No fluctuation was detected in the tumour either by abdominal or pelvic examination. The diagnosis arrived at

was "Two tumours of somewhat doubtful nature, the central one probably ovarian and that on the left side a distended Fallopian tube." I decided to operate with as little delay as possible.

On Dec. 11th Mr Stormont Murray administered ether, and assisted by Dr Copeland, Dr Fawson Lee also being present, I proceeded to open the patient's abdomen. Difficulty was experienced at the very outset of the operation, owing to the omentum being extensively adherent to the abdominal wall in the line of incision, it being necessary to enlarge the opening to the extent of five inches. On introducing my fingers into the abdominal cavity there seemed to be four distinct tumours—the central swelling, the body of the uterus, and the left Fallopian tube enormously distended and bent upon itself in the shape of a horseshoe. The central tumour was intimately connected with the posterior surface of the uterus, its lower portion being fixed in the recto-vaginal pouch, and thus pushing the uterus upwards and forwards.

FIG 1

A distended Fallopian tube

The whole surface of the tumour was surrounded by adherent intestine and omentum, the separation of which was most difficult and tedious. I succeeded, however, in removing the tumour unruptured and controlled the rather free hæmorrhage by packing sponges into Douglas's pouch. The tumour on the left side was then dealt with, and its enucleation and removal gave considerable trouble owing to extensive intestinal and pelvic adhesions. In both cases the ovaries were so closely attached to the uterus that it was impossible to ligature the tubes without including fragments of ovarian tissue. The adherent omentum was then separated from the abdominal peritoneum and all the bleeding points were tied with fine silk. I did not wash out the peritoneal cavity or drain, but carefully sponged out the pelvis and then closed the wound with silk sutures. The operation lasted over two hours and a half but the patient after removal to bed had a capital pulse and did not show any signs of exhaustion. She rallied

² Text-book of Chemical Physiology and Pathology, 1891 p 300

myelitis is rare.¹ Dr Wilks in his "Lectures on Diseases of the Nervous System" only quotes two cases and Dr Pye-Smith mentions a case in "Fagge's Medicine." The cause in this case was most likely exposure to wet and cold and most probably the former had more to do with it than the latter. The suddenness of the attack was well marked, and retention of urine was one of the earliest symptoms. The patient improved gradually but his improvement was seen from the day of his admission, so that it is somewhat improbable that the iodide of potassium had any beneficial effect, as this was not prescribed until two days after his admission to hospital. The absence of bedsores was in the patient's favour and every care was taken in preventing them, the patient being put on a water bed and the skin of the back, buttocks and heels daily washed with methylated spirit and dusted with zinc and starch powder. One half of the spinal cord appears to have been more involved than the other half, as the paralysis was always more marked on the right side.

S G—, aged forty three, a trawler, was admitted on July 28th, 1891, complaining of paralysis of the lower extremities, slight pain in the lumbar region and retention of urine. The patient was a strongly built, dark haired man about six feet in height. He gave the following history. A week before the commencement of his present illness he was cutting grass with a pair of shears and had to sit and lie about on the wet ground. He continued this occupation for a week. On July 18th he noticed that his feet felt "numb and dead" and in the afternoon he could not pass his urine and was obliged to send for his doctor and have it drawn off. The feeling of numbness extended from the lower part of the abdomen and down the thighs and legs. On the 21st his legs felt worse and he could not walk, the right leg was worse than the left. At the beginning of his illness he suffered from pain in the back, this was more marked on trying to sit up in bed. Fifteen years ago he had gonorrhœa, but had never had syphilis. He had been strong and healthy up to the time of his present illness. The heart and lungs were normal. Temperature 99°, pulse 68 full, regular and not easily compressible. The legs and thighs were well developed, but the muscles felt distinctly flabby. He had complete paralysis of the right leg, but he could move the left leg very slightly. There was no plantar or cremasteric reflex on either side. Both patellar reflexes were increased, but more so on the right than on the left side. Ankle-clonus was well marked on both sides. Sensation was altered on the plantar surface of the feet, he could not feel the prick of a pin, but stated that he felt something touching him. This modified sensation was also present on the legs and thighs, but was more marked on the plantar surface of the feet. The catheter was used to draw off urine, and as the urine was alkaline and ammoniacal his bladder was washed out twice a day with hot boracic lotion. His bowels were constipated, but before the illness he had always been regular. He was given a light diet, and a mixture of iodide of potassium (5 gr) with carbonate of ammonia and gentian was ordered. This mixture was continued for three weeks. He had then gained more power in the legs, the right leg was still worse than the left and the muscles felt softer. His bowels were very troublesome and only acted after an enema. He continued to improve and on Oct 8th the following note was made. The patient's gut has much improved, he can now walk long distances without fatigue but in walking he seems to bring his feet rather too suddenly down, and sometimes he totters slightly. The muscles of both legs feel much firmer. The right knee jerk is still much increased and the left slightly, there is no ankle clonus. He passes urine about every five hours during the day and gets up once or twice in the night to pass it. He has been taking four minima of liquor strychniæ three times a day since Aug 19th. The patient left the hospital on Oct. 13th, and has been under observation since. He has been in his usual health for some months. He can walk long distances without fatigue and has resumed his occupation as a trawler. The muscles of both legs have completely regained their normal tone, his gait is quite natural and he has no increase of knee-jerks. The urine is acid and he has no trouble in passing it. His general health is now very good.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Effects of Iodides on Arterial Tension and Excretion of Urates

AN ordinary meeting of this Society was held on Jan 10th, Dr George Harley, Vice President, in the chair.

A telegram from the President was read announcing his inability to be present and asking the Society to welcome Dr Mirza Ali, chief physician to the Shah and Professor of Medicine in the University of Teheran, who was on a visit to this country. He was accompanied by Hussein Kuli Khan, Secretary of the Persian Legation, and he presented to the library of the Society copies of his medical works in Persian and French.

Dr A. HAIG read a paper on the Effects of the Iodides on Arterial Tension and the Excretion of Urates. He referred to an article of his in vol lxxi of the Transactions on drugs which diminished the excretion of urates. The list of substances which had this action had now been greatly enlarged and he believed that the iodides must be added to it. He also believed that the action of these substances on the solubility and excretion of urates would explain a large part of their value and utility in medicine and surgery, just as he had previously said elsewhere with regard to opium and mercury, which acted in the same way. He was at first misled by his results with the iodides, and was further hindered by their affecting the process which he had used for the estimation of uric acid (Haycraft's). These difficulties were, however, got over, and with greater knowledge and experience of the working of certain laws which govern the excretion of urates and of water he now believed that it was possible to speak more decidedly as to the action of iodides. One of these laws was that first formulated by the writer at the beginning of 1889¹ "that, *ceteris paribus*, arterial tension varied with the uric acid that was circulating in the blood." Another was that from day to day and from hour to hour in physiological conditions the urinary water varied inversely as the uric acid was excreted along with it. Another was that in physiological conditions the excretion of urates in the urine varied inversely as the acidity of the urine. And another, that the amount of urate in the urine was relatively to the urea to a certain extent an index of the amount of urate passing through the blood. From these it followed that arterial tension varied with the amount of uric acid that was being excreted in the urine. But arterial tension meant contracted arterioles, and contracted arterioles meant that water had difficulty in passing the kidneys, as was shown to be the case in the parallel action of digitalis and other drugs which contracted the arterioles, and this was the reason why the urinary water varied inversely as the uric acid. The diuretic action of iodides was well known, and the writer showed four figures which demonstrated that at the time an iodide was causing diuresis it was also causing a diminished excretion of urate and that the one thing was related to the other as cause and effect. The figures also showed well the inverse relation of urates and water in excretion, also that under the influence of iodides the excretion of urate ceased for a time to bear its usual inverse relation to acidity. But the writer pointed out that some twenty drugs, or rather groups of drugs, all diminished the excretion of uric acid in the urine, and at the time they did this they produced also relaxed arterioles, lowered arterial tension and diuresis. Then iodides could be classed along with these drugs, and as the latter could further be broken up into three groups according to the way in which they produced the diminished excretion of uric acid it might be possible to say which of the groups the iodides most resembled in their mode of action. He pointed out how this action of iodides on the solubility of urates and so on the contraction of arterioles, enabled us to explain all their most important effects in physiology and pathology, just as he had previously pointed out in the case of opium and mercury. Lastly, he referred to his previous writings on uric acid as a cause of high arterial tension and suggested that there was no possible explanation of the parallel action of all these drugs except that which he had given—namely that urates contracted the arterioles all over the body and

¹ Brit. Med. Jour., vol. I p 291.

six grains, Mr Lyster² of Coleshill also described a case where recovery followed after a patient had probably taken two grains and a half of the alkaloid, and Mr Fegen⁴ described the symptoms in a fatal case where it was supposed that from two to three grains of the poison had been taken. Dr Bingham⁵ of Alfreton was also engaged with a fatal case of poisoning from this drug. Dr Wyman's suggestion with regard to the continued administration of chloroform appears a practical one. With regard to some of the antidotes which have been more recently recommended, Anrep⁶ thinks urethan superior to chloral hydrate and advises the administration of one to one and a half drachms when a poisonous dose of strychnine has been taken. Dr C Sanquirico⁷ recommends intravenous injections of a considerable quantity of an 8 per cent. soda solution, which will produce an active diuresis and assist in eliminating the poison. J S Horsley⁸ in a case of strychnine poisoning injected apomorphine in doses of from one fifteenth to one-tenth of a grain subcutaneously and "completely subdued the convulsions and eventually successfully antagonised the excitant alkaloid."

At 3 A.M. on April 12th, 1892, two women were brought to the hospital said to be suffering from the effects of poison through eating tinned salmon. It appeared that they had both dined off tinned salmon at 7 P.M. on the evening of the 11th and supped off the same substance at 2 A.M. on the 12th. But one of the women, E S—, also stated that a man who left their house just before their supper at 2 A.M. had given them each "three long narrow pills" (capsules). The exact time at which the unfortunate women swallowed the pills could not be ascertained. At 2.30 A.M. their screams aroused the landlord, and a policeman who was called in brought them to the hospital, having first given them each a mustard and water emetic, but without the production of vomiting. One of the women A. M—, died on the way to the hospital. The other, E S—, was alive and when first seen was sitting in a chair apparently quite well. Within a minute or two she had a convulsive attack in which owing to the straightening of her back, she slipped off the chair on to the floor. An emetic (40 gr. of sulphate of zinc) was given, but without effect. The stomach was then washed out several times with tepid water and half a tumblerful of thick charcoal and water given her to drink. During this time the patient was having convulsive attacks every four or five minutes. The attacks were of the following character. The patient suddenly became quite stiff, the back rigid and arched, with rigid flexure of arms and rigid extension of legs and feet. The rigidity was very marked during the greater portion of the attacks, which usually lasted from one minute to a minute and a half. But towards the end of the attacks, sometimes from the beginning, there were spasmodic movements of legs, arms and back. The pupils were equal, semi-dilated and reacted to light. The pulse was even but rather accelerated. Respiration seemed to stop during the attacks. The patient recovered from these fits almost as quickly as she entered them and in the intervals between them was perfectly conscious and rational only complaining of a little stiffness of the legs and dryness of the throat. The attacks came on at fairly regular intervals but whenever she received any external stimulus—such as change of position, the attempt to drink or even, on one or two occasions the sound of pouring fluid into a glass—she had a fresh attack. The attacks were frequently preceded by a loud cry. As the fits did not abate in frequency or severity chloroform was administered at about 4.15 A.M. and while under its influence the patient was removed to Christian ward. While being put to bed the effect of the chloroform partially passed off and the patient had another attack, in which she became greatly cyanosed and respiration was suspended. It was only after some minutes of artificial respiration that she again began to breathe. Chloroform was then again administered, and the patient was kept deeply under its influence until 7.30 A.M., during the whole time of its administration breathing quietly and maintaining a firm, steady pulse. At 7.30 it was discontinued under a false hope of security, and as its effects began to wear off the patient had three more convulsive attacks in the last of which she died although artificial respiration and chloroform were again resorted to. Death took place with extreme cyanosis at 7.45 A.M., about five hours and a half after swallowing the pills. The urine which had been retained since admission, was drawn off by catheter at 7 A.M., and was found

to contain a trace of albumen and a deposit of urates. It was afterwards analysed by Mr White, the hospital pharmacist, who discovered in it one-twelfth of a grain of strychnine.

The post-mortem examination showed no sign of any organic disease in either case. In both cases the blood was very dark and fluid. In the case of E S— the right side of the heart was distended with soft, black clot and the lungs were full of blood and were oedematous. In the case of A. M— both sides of the heart were empty, but the lungs were in the same condition as those of E S—. The stomachs, with their contents, a portion of liver and one kidney from each case were removed and forwarded to Dr Stevenson, Government analyst for examination. He reported the results of his analysis as follows:

E S—Vomit contained	1.46 gr strychnine.
Stomach and contents	1.60 "
Liver and kidney	0.20 "
Total	3.26 "
A. M—Stomach and contents	6.39 "
Liver and kidney	0.40 "
Total	6.79 "

Remarks by Dr WYMAN.—The symptoms as above detailed in the case of E S—, coupled with the fact that A. M— had already died from the effects of presumably the same poison, were so characteristic as to be unmistakable. As regards the treatment it may be said that as long as E S— remained under the influence of chloroform she appeared to be in no danger, at any rate from the effects of the poison. And it is reasonable to suppose that if the administration had been continued until the poison had had time to be eliminated from the system by the urine the patient might have recovered. That the administration would have had to have been continued for some twelve hours or more seems probable from the fact that only one twelfth of a grain was so got rid of during the five hours she was under treatment. From this, then, it would seem that if the chloroform treatment is used at all it must be continued until all trace of the poison has disappeared. This can only be determined by watching very carefully for any sign of twitching of muscles, especially of those about the eye and mouth during the period immediately succeeding the cessation of the administration of chloroform. If the slightest twitching is observed chloroform should be again administered. Unfortunately, the process of separating the strychnine from the urine is rather a lengthy one in point of time and therefore not likely to be of much value in this respect. Charcoal readily absorbs strychnine and other vegetable alkaloids and is therefore a useful remedy. It should be given in large quantities, allowed to remain in the stomach for ten minutes or a quarter of an hour and then washed out with the stomach pump, for if allowed to remain and pass on into the intestines the strychnine will again be given off and carried into the circulation. The process should be repeated two or three times. Another point of great importance from a legal point of view which arose in this case is the question, When, with a view of obtaining a dying declaration, is the medical attendant justified in telling the patient that he is dying? Any description of the murderer or other statement concerning the crime cannot be brought as evidence against a prisoner unless it can be proved that the victim at the time of giving it believed that he was actually dying and would not live many hours. In this case I did not feel myself justified in telling the patient that she was dying and therefore her statements were not allowed as evidence at the trial. It must be remembered that a living witness is better than a dead one, and anything tending to add to the risks of death in a doubtful case should be avoided. If on the other hand, there can be no doubt that a fatal result is imminent, I think it is the medical attendant's duty to tell the patient plainly what his condition is, and so possibly assist justice and protect other people from a similar fate.

TORBAY HOSPITAL, TORQUAY

A CASE OF ACUTE MYELITIS, COMPLETE RECOVERY

(Under the care of Dr POWELL.)

As Mr Watson, the house surgeon, to whom we are indebted for the notes, observes, complete recovery from acute

² THE LANCET, vol. i. 1889 p. 613. ⁴ Ibid. vol. i. 1889 p. 951.

⁵ Ibid., vol. i. 1889 p. 332.

⁶ Sajous 1878 vol. v p. 125.

⁸ Ibid., 1892 vol. v p. 25.

from India had uterine catarrh and descent with retroversion. After the application of two zinc alum points, without rest in bed and without a pessary, the uterus had returned into its place and the backward displacement had gone. With respect to dyspareunia, this was a wide term and there were at least two principal forms—one in which the pain was associated with spasm of the vaginal orifice and the other due to deep tenderness, generally from some inflammation about the ovary or tube. In such a case there was often tenderness on pressing the uterus, which was not really tender but pressed against the adjacent tender organ. It was often described as tenderness of the uterus, but incorrectly—Dr GERVIS did not agree with the opinion that backward displacement of the uterus was but a stage of prolapse, although unquestionably retroflexion without descent was of far less importance than when it occurred with it. Speaking generally, he thought that flexions, if uncomplicated, were of but moderate importance, but if associated with cervical stenosis or endometritis they became of considerable importance. He further believed that in many of the cases where there was associated ovarian pain the pain was due to a subovitis whose starting point was endometritis, and that this endometritis was in its turn due to the interference with normal menstruation induced by the flexion—Dr HERMAN, in reply, said that, in his opinion, uncomplicated retroversion or flexion of the uterus caused no symptom of any kind. Had the cases on which the paper was based not been complicated the patients would not have applied for treatment. Some years ago it was believed by many that every complication that existed along with a displaced uterus was the consequence of the displacement. Some had gone to the opposite extreme and regarded backward displacement of the uterus as being always a bagatelle and the presence of symptoms with it merely a coincidence. He had compiled this paper to help himself to a correct idea of the frequency with which backward displacement was really the cause of symptoms existing along with it. It was not possible to settle the question of reporting individual cases because the interpretation of individual cases depended on the general principles previously adopted by the observer, which he could not prevent from biasing his judgment, therefore he (Dr Herman) had adopted the statistical method set forth in his paper. He did not accept the views put forth by Dr Gervis, and for two reasons. First, if retention of menses was produced by flexion of the uterus, how was it that no one had ever yet produced a uterus dilated by the retained fluid? Secondly, if displacement backward caused the ovaries to be tender by producing salpingitis and oöphoritis, how was it that (as the displacement was not unilateral) this state of things was produced three times as often on the left side as on the right?

Dr CULLINGWORTH next communicated a note supplementary to a paper read before the Society on April 2nd, 1890 on Vaginal Hysterectomy, giving the subsequent history of the cases. Of these, one lived for two years and two months, one for a few days short of two years, and the third for a little over seventeen months. Two enjoyed perfect health until within a few weeks of their death. In each of these cases death resulted from intestinal obstruction, the cause of which in one case remains unknown, in the other it was pelvic adhesions, the only signs of recurrence being a single enlarged gland and a small ulcer in the vaginal roof. In the third case the history showed restoration to fairly good health for six or eight months then gradual failure for twelve months, and finally six months of absolute confinement to bed, death occurring from kidney disease due apparently to impaction of the bladder and ureters in the recurrent growth. The patients with columnar celled carcinoma lived longer than the one in whom the disease was of the squamous celled variety—Dr PLAYFAIR said in his opinion the whole subject of the surgical treatment of uterine cancer was still *sub judice*, and neither total extirpation nor supra-vaginal amputation could be considered, so far as our present experience went, as anything but very unsatisfactory procedures, affording the patient the chance of prolonging her life in comfort for a greater or less length of time, but which, so far as existing evidence went to show, did not give a reasonable hope of complete cure. The important point to settle was which of these procedures affords the patient the best chance for the future? He had operated in a large number of cases by supra-vaginal amputation, but sooner or later the disease had recurred in all. Nor is the immediate danger altogether a negligible quantity. He did not know of any reliable statistics on this point, but he observed that in a recent paper read at the Gynecological

Society advocating this procedure death had been stated to follow in two out of twenty four cases (about 8 per cent.), which represents an initial mortality but little less than that of total extirpation. He thought it must be admitted that if from improved technique the mortality of total extirpation could be shown to be not materially greater than that of supra-vaginal amputation, it must be considered the most surgically correct and hopeful procedure. No surgeon in his senses would remove part of a cancerous organ if he could remove the whole of it without much more danger. So far as recent statistics went the tendency seemed to show that total extirpation, unsatisfactory though it was, would come more and more into favour. It had been argued by Dr John Williams and others that in epithelial cancer of the cervix the tendency of the disease was to spread laterally on to the vaginal walls and not upwards into the uterus, and that we might therefore safely rely on supra-vaginal amputation. This had always seemed to him (Dr Playfair) a dangerous doctrine, and in the uterus [now shown] which he had removed by total extirpation the disease was apparently limited to the cervical portion so far as naked eye appearances went. Let in the section shown under the microscope, taken from near the fundus and right away from the apparently diseased textures there were marked evidences of malignant infiltration. Similar specimens had been shown by Olshausen and others, so that the theory that "the epithelial variety of cancer can be safely considered to be limited to the cervix" seems untenable.—Dr LEWERS said that a conclusion as to whether vaginal hysterectomy or supra-vaginal amputation of the cervix was the better operation could only be arrived at by comparing the results, both as to mortality and recurrence, obtained by these operations in a large number of cases. He did not think Dr Cullingworth's cases were at all encouraging to those who were the advocates of vaginal hysterectomy, on the contrary, these cases made it evident there was an appreciable risk of intestinal obstruction as a remote consequence of the operation. Referring to his own patients, he had nineteen cases of supra-vaginal amputation without a death, and six of these were free from recurrence for two years and upwards after the operation. As regards the body of the uterus being involved in some cases, as mentioned by Dr Playfair, the point was that generally when there was extension to the body of the uterus there was also infiltration of the tissue round the cervix, making these cases unsuitable for either operation. He thought that in exceptional cases vaginal hysterectomy was required for cancer of the cervix, and he had shown a specimen in point recently.—Dr HEXWOOD SMITH considered that the result in Dr Cullingworth's cases told more in favour of supra-vaginal amputation of the cervix, as two of the deaths were owing to obstruction due to adhesion of the bowel to the pelvic wound. He suggested the advisability of drawing down the wounded edges into the vagina so as to present a smooth surface on the peritoneal aspect. It seemed to him that, except in cases of primary cancer of the fundus uteri, the supra-vaginal amputation held out the better prospect of success at rather less risk to the patient.—Dr GERVIS thought Dr Playfair took too gloomy a view of the progress in cases of supra-vaginal amputation of the cervix, especially where the operation was undertaken for an epithelioma springing from the vaginal aspect of the cervix, or which, commencing in the cervical canal, had spread laterally rather than upwards.—Dr WILLIAM DUNCAN pointed out that at the present moment there are no statistics showing the mortality in a large series of cases in which vaginal extirpation and supra-vaginal amputation for cancer had been respectively performed in this country, and that therefore we were not in a position to dogmatise on the subject. The best series of vaginal extirpations he knew of was that of Professor Sinclair of Manchester, whose mortality was certainly as small as that of supra-vaginal amputation when performed by the most skilful operators. He must confess to a change of opinion with regard to the two operations to that he expressed in a paper on Extirpation of the Uterus read before the Obstetrical Society in 1885 and he thought that now as the mortality of the two operations can be reduced to almost (if not quite) the same level, total extirpation was the more scientific procedure, even though it were the more difficult to perform.—Dr CULLINGWORTH, in reply, said he saw no reason to modify the opinion he expressed in the discussion on his hysterectomy paper as to the respective merits of supra-vaginal amputation and total extirpation. He thought Dr Playfair's specimen a very striking illustration of the risk run

raised arterial tension, while their absence from the blood stream, however produced, allowed these vessels to dilate. The action of iodides on arterial tension was thus completely explained by their influence on the solubility and excretion of urates.

Dr GEORGE HABLEY said that in latter years pathology had entered on a new phase, the scalpel and the microscope giving place to the test tube and the balance. He held that it was through chemistry alone that the secrets of morbid action could be discovered. The diseases arising from anomalies in the behaviour of uric acid were manifold, and he could bear personal testimony to the fact that when colchicum could not be borne in gout iodide of potassium would give great relief. Certain individuals were more prone to form uric acid than others, so were certain families and in certain districts. Uric acid was very common among the ancient Egyptians. Many theories had been advanced as to the cause of its formation, it had been thought to be a transition stage in the formation of urea and it had been considered to be due to a too high oxidation. The dog had no uric acid in his urine, though he fed much as his master did, and the calf had uric acid in its urine though the cow had none. These peculiarities were as yet unexplained.

Professor MIRZA ALI said that gout was not unknown in Persia, but it was only met with among the rich, the poor did not eat animal flesh at all. The only collections of uric acid found were in the joints, he had not met with them in the kidneys or bladder.

Sir WILLIAM ROBERTS found that he could scarcely intervene in the discussion with much advantage. He had been following Dr Haig's work for years, but he thought that a too continuous study of one subject led to something like mesmeric dazing and diminished an author's experimental resources. His three years' work on this question had led him in an opposite direction to Dr Haig. He had found that the uric acid varied conformably with the amount of water. Dr Haig had stated that the alkalies increased the capacity of the blood for dissolving urates, but no general statement such as this could be opposite, for what was true with regard to uric acid was false for urates. It appeared to him chemically impossible that uric acid could exist free within the body, and according to his own reflections it was unnecessary to assist its solubility. He knew of nothing which affected the solubility of bi-urates in blood serum outside the body, and his experience was that rendering the serum more alkaline rather diminished its solvent power. He regarded uric acid as harmless so long as it remained in solution, it only became troublesome when thrown out. He doubted more and more whether uric acid covered the whole field of gout or whether the latter was not a much larger subject. He was inclined rather to believe that if uric acid were withdrawn altogether gout would still remain as a clinical and pathological entity recognisable as such.

Dr SANSOM said that the paper of Dr Haig and the contribution of Sir William Roberts were directed rather to what used to be called the "humeral" aspect of the subject. Though he did not wish to throw doubt on this side of the question, he believed it should occupy the background, being deuteropathic rather than protopathic. That the iodides had a marvellous power of reducing arterial tension could not be denied, in sacculated aneurysms and in angina pectoris their favourable action in relieving pain and distress was marked. But he questioned if the relaxation of intra-arterial strain were really due to an action on the fluids of the body, he regarded it rather as some action through the nervous mechanism whereby the arterial tension was relieved. Iodide of ethyl inhaled was often followed rapidly by the relief of symptoms, and he doubted if, in the few seconds which elapsed, the drug could not in the manner Dr Haig suggested. The amount of arterial tension depended not only on the contraction of the arterioles but on the force of the left ventricle, and the free excretion or otherwise of urine depended on both these factors. It was a question of correlation of peripheral resistance with a weak or strong left ventricle. He asked if in an attack of acute gout the arterioles were usually contracted, he had seen marked diastolic pulse during this stage. He thought the evidence brought forward must be carefully weighed in the light of clinical experience.

Dr HAIG in reply, said that, as to the proneness of certain groups of people to the formation of uric acid, he doubted whether there was really a plus formation or whether more uric acid was not retained in their bodies. Excessive formation was entirely due to meat diet. Gout and calculus were

to a certain extent the opposites of each other. Gout occurred with a minus excretion, the uric acid being retained, calculus occurred with a plus excretion, the uric acid being cast off. Sir William Roberts had obtained his opposite results by working in the laboratory. He himself could make the headache vary absolutely with the amount of uric acid present in the body. He had experimented largely with nitrite of amyl and nitro-glycerine. It took seven or eight minutes before the maximum effect on arterial tension was produced with these drugs, and this allowed ample time for the substance to act chemically on the blood. There was very little uric acid in the blood during an attack of gout and the arterioles at that time were relaxed.

OBSTETRICAL SOCIETY OF LONDON

Backward Displacements of the Uterus — Vaginal Hysterectomy

A MEETING was held on the 4th inst., Dr J. Watt Black, President, in the chair.

The following specimens were shown —

Dr HANDFIELD JONES. Calcification of Fibroid.

Dr LEITH NAPIER. (1) Fibro-myoma undergoing Degeneration, (2) Several Gynecological Instruments.

Dr WHEATON. (1) Bony Parts removed from Dermoid Tumour, (2) Bilateral Cephal hæmatoma.

A paper by Dr HERMAN on the Frequency of the Local Symptoms associated with Backward Displacements of the Uterus was then read, the communication being based on an analysis of 407 cases of the abnormality. He found that chronic pain of some kind is present in nine-tenths of the cases of backward displacement of the uterus. The most frequent seat of pain is the back, generally the sacral region. Next most often come sensations of descent and unilateral pain, chiefly in the ovarian region, cases of left-sided pain outnumbering those of right-sided pain in the proportion of three to one. In a small proportion lower abdominal pain is the chief complaint, and in a very small minority trouble in locomotion is the prominent symptom. Pain in defecation is present in less than half the cases. In the majority of the cases in which it is present it is accounted for either by constipation or by morbid conditions of the rectum. Dr Herman estimates the proportion of cases of backward displacement of the uterus in which the displacement is the sole cause of painful defecation at about one in nine. Backward displacement of the uterus has no appreciable effect as a cause of painful micturition, but bladder irritation due solely to the displacement is present in about one case in five. Leucorrhœa is not commoner in cases of backward displacement of the uterus than among other patients. Dyspareunia is present in at least one-sixth, and probably in a large number, absent in at least one-seventh. Dr HANDFIELD JONES pointed out that Dr Herman, while tracing the connexion of pain at various points with backward displacement of the uterus, had made no reference to the condition of the misplaced organ, for in some cases it caused no symptoms, whilst when inflamed and acutely tender it did give rise to great suffering during defecation or coitus. Sometimes the ovaries were also prolapsed, enlarged and tender and were the real cause of the pain complained of. — Dr CHAMPEYNS agreed that the explanation of the frequency of left-sided pain was that that side was the "weaker," that this was not due to pelvic causes was proved by the frequency of other left-sided pains, and especially left sub-mammary pain. Pain in the bowels was generally due to intestinal causes. The unimpregnated uterus could not conceivably exert any injurious pressure on either the bowel or the bladder, its weight out of the body was about an ounce, and as about half of this was lost by the pressure of the surrounding soft parts, it could only exert a downward pressure of some half ounce. The only other theory of pressure was that due to impaction, the conjugate of the pelvis was about four inches, the extreme length of the uterus not more than three, if flexed still less, so that impaction was impossible. The immediate effect of bearing down was not to increase but to diminish retroversion and flexion, the centre of the pelvic diaphragm descending more than the sides. Generally speaking, backward displacements were signs of descent. He was rather surprised to hear that catarrh was not common among patients with backward displacement. In his experience the association was very common, and both were signs of absence of tone in the pelvic soft parts. He had seen two cases a little while ago which illustrated this association—two ladies

SHEFFIELD MEDICO CHIRURGICAL SOCIETY—At the meeting on Dec 22nd, 1892, the President, Mr Simeon Snell, F R C S Edin, in the chair, the following cases, notes and specimens were brought forward.—Dr COCKING showed two cases of Ataxic Paraplegia (1) a woman aged twenty five, single, (2) a woman aged forty six, single, a governess. In the latter case there was diplopia four years ago, which soon passed off and was followed by weakness of the legs and ataxy, her gait was unsteady the unsteadiness increasing on turning and on closing the eyes, the pupils were equal, reacted sluggishly to light, and contracted slightly on accommodation, the discs were greyish, the knee-jerks had increased. The ataxy in both cases was unmistakable, but differed in character from that of locomotor ataxy. In neither case was there any evidence of intracranial disease nor of syphilis, or any history of injury or exposure. There was no neurotic family history.—Dr PORTER read the notes and showed photographs of two cases of Progressive Muscular Atrophy. In one patient aged fifty the atrophy commenced in the muscles of the leg, thus resembling the "peroneal type" of this disease. There was an entire absence of family history and the disease had run a very acute course. In the other case the atrophy had begun in the muscles of the scapula and upper arm and there had been marked lordosis and wing like projection of the scapula, resembling in several respects cases of simple idiopathic atrophy. In this case, again, there was no family history and the disease ran a very acute course, involving the forearms and hands in a typical manner. Death ensued ultimately from respiratory paralysis.—Dr WILKINSON read short notes of a case of Acute Ulcerative Colitis in a man aged forty three, who was admitted to hospital three weeks after the commencement of his illness and died three days after admission. The onset was acute, the principal symptoms being pain in the abdomen, diarrhoea with tenesmus, the passing of blood and mucus and rapid wasting. At the necropsy extensive and deep ulceration was found throughout the whole large intestine.—The PRESIDENT introduced patients with Herpes Frontalis, Embolism of the Central Artery of the Retina, Epicanthus &c. He also read notes of a peculiar and a rare case of Associated Movement of the Eyelid.—Dr DAVY brought forward a child with a hard, painless Abdominal Tumour situated in the left part of the epigastrium.—Mr RICHARD FAYELL showed an Ovarian Dermoid Tumour which he had removed from a woman who was three months and a half advanced in pregnancy. The patient made a good recovery and there was no attempt to abort.—At the conclusion of the meeting several specimens were shown.

Reviews and Notices of Books.

The Diseases of Children Medical and Surgical By HENRY ASHBY, M.D., F.R.C.P., and G. A. WRIGHT, M.B., F.R.C.S. Second Edition. London Longmans, Green and Co 1892.

THIS work has taken a recognised place in medical literature, and the appearance of a second edition shows that it is appreciated by the profession. It is one of the most thorough and complete manuals on diseases of children with which we are acquainted. The collaboration of a physician and a surgeon in the preparation of such a work is obviously a wise arrangement, and the wonder is that it has not become the rule. What would be thought of a physician or a surgeon who should propose to write a systematic treatise embracing the whole field of medicine and surgery as they relate to adults? Yet the difficulties of such a project are only a little less great in the case of children. The collaboration of Dr Ashby and Mr Wright saves this work from that sketchiness and scarpiness which are the bane of works upon diseases of children. The treatment of each subject is full and adequate, and no important disease is slurred over or merely outlined because it lies outside the range of the writer's practice. The present edition has been thoroughly revised, and several of the sections have been entirely re-written. Many clinical reports of interesting cases and forty new woodcuts, most of them origi-

nal, have been added. The authors hope that their work may now be accepted as presenting as far as possible a complete account of Diseases of Childhood. In reviewing a second edition we do not feel it necessary to enter into details. We have tested this work at many points, and always with a satisfactory result. No doubt there are not a few statements and recommendations which we should be disposed to contest, but this must always be so in such a wide and debatable field as that of medicine and surgery. The style of the work is plain and unadorned, there is no striving after brilliancy nor any apeing of originality. The authors have evidently aimed exclusively at accuracy, simplicity and thoroughness and we think they have succeeded. The woodcuts are numerous and well executed, but some of them are somewhat repulsive. The Horatian maxim, "Ne pueros coram populo Medea trucidet" is a good one for the stager, and we doubt if there is much advantage in multiplying ghastly representations of disease. Such aids to knowledge have their uses, but if employed too freely they seriously detract from the pleasure with which we contemplate the volume containing them. We can endorse the authors' claim that the information given is well up to date, and we have not noticed any important omissions. The therapeutic recommendations are for the most part plain and show common sense. We can heartily recommend this volume as ably fulfilling its design, and we feel sure it will continue to occupy an honourable place in medical literature.

Finger Prints By FRANCIS GALTON, F.R.S. London Macmillan. 1892. Pp 216

MR. GALTON'S works are always good reading. They deal with subjects and problems the discussion of which is exceedingly interesting, and which, though they are, so to speak, at everyone's elbow, have never been thoroughly and carefully worked out. Mr Galton's works on the Heredity of Genius, Natural Inheritance, and Human Faculty are examples of these investigations. In the present treatise he has taken up an apparently trivial subject, and by the number and accuracy of the observations he has made upon it has shown that it constitutes an exceedingly valuable means of identification of different persons even after the lapse of many years. If the palmar surface of the hand or the plantar surface of the foot be examined they are found to present a number of creases to the number and direction of which in the old days of cheiromancy great importance was attached, and also a number of minute parallel ridges which pursue curved courses, and, commencing in the hand just below the wrist, become very distinct over the thenar and hypothenar eminences are less marked over the first and second phalanges and are most pronounced on the pulps of the last phalanges. Their number varies from forty to fifty or sixty to the inch and they represent the arrangement of the nervous and vascular papillae which belong to the dermis. Mr Galton states that in China—whose inhabitants are always the first people in curious knowledge—India and elsewhere the impression of the tip of the finger has been frequently used as a sign manual for documents of importance where the persons concerned were unable to read or write. The first person who employed them for this means with effect was Sir Wm. Herschell, who, when in Bengal, found it so difficult to obtain credence to the signatures of the natives that he thought he would use the signature of the hand itself, chiefly made with the intention of frightening the man who made it from afterwards denying his formal act. The impression, moreover, proved so good that Sir Wm. Herschell became convinced that the same method might be further utilised.

The use of the ridges does not seem to be clearly made out. Mr Galton thinks they exist primarily to raise the mouths of

by those who practised the minor operation of leaving behind an unsuspected focus of cancer in the uterus. The fact of even the occasional occurrence of concomitant disease in the body of the uterus furnished a strong argument in favour of the removal of the whole organ even when the cervix alone appeared to be affected. Dr Lewers' great success in the partial operation naturally made him strongly advocate it, but the number of those who agreed with him was steadily diminishing, and he (Dr Cullingworth) had little doubt that total extirpation would come to be recognised as the more satisfactory method of dealing with the majority of those cases in which a radical operation of any kind was permissible. The meeting then adjourned.

PROVINCIAL MEDICAL SOCIETIES

FORFARSHIRE MEDICAL ASSOCIATION—A quarterly meeting of the Forfarshire Medical Association took place at the Anatomy Class room, University College, Dundee, on Friday, Dec 23rd, Dr Rorie, President, in the chair.—Professor WATMOUTH REID gave notes of a Case of Urohemato porphyrin uræa from Sulphonal Poisoning, of which the following is an abstract. Hemato porphyrin uræa is not uncommon in connexion with the administration of sulphonal. Stokvis, Jolles, Salkowski and Hammarsten have recorded such cases. In the case brought before the Society an elderly woman had taken large doses of sulphonal without medical advice and the urine presented the characteristic deep cherry red colour. The pigment was unfortunately extracted by the lead method from the small sample obtained and presented the spectra of urohemato porphyrin as given by Munn in acid and alkaline solution and after treatment with zinc chloride and ammonia. No more could be obtained for extraction with Salkowski's barium method or Garrod's earthy phosphate method, since the case was rapidly fatal. The connexion between sulphonal and hemato porphyrin uræa is very obscure. A recent paper by Smith, working under Baumann, deals with the changes undergone by sulphonal in the organism. Kast had previously shown that its administration did not increase the output of sulphuric acid and that easily soluble organic sulphur compounds appeared in the urine. Smith, considering the possible excretory products—ethyl sulphuric acid and sulpho acetic acid—because he could not find the latter concluded in favour of the former, but the substance was not isolated. The fate of sulphonal, then, is as yet unknown. No direct action of sulphonal upon blood, aerated or otherwise, in the incubator at 40° C, could be obtained by the author, even when finely divided fresh liver or spleen was added to the mixture, indeed, no disintegrating action was to be expected from such a stable compound. Neither could any hemato-porphyrin like pigment be obtained by acting upon bilirubin in alkaline solution at 40° C. Two possible explanations of an indirect action of sulphonal occur to one. (1) On the assumption that hemato-porphyrin is normally produced (traces in normal urine) but subsequently reduced in certain organs to a urobilin like body (Nencki and Lieber), it is possible that interference with such organs might lead to the appearance of larger amounts of hemato-porphyrin in urine. (2) Bilirubin being isomeric with hemato-porphyrin, it is also possible that the constipating action of sulphonal might lead to an abnormal amount of absorption of the former from the bowel and that it might appear in the form of the latter in urine. In conclusion it may be mentioned that the action of sulphonal in producing hemato porphyrin uræa is subject to idiosyncrasy. A sample affecting one patient may leave another untouched, and it is not necessary that in the event of its producing abnormal pigment excretion that that pigment should appear as hemato-porphyrin, as a recent case of Quinke's has shown.—Dr MCGILLIVRAY exhibited and read notes of a case of Persistent Papillary Membrane with Congenital Dislocation of the Lenses and Corectopia in both Eyes. He also read notes of another case of Persistent Papillary Membrane in one Eye. In the first case there was a history of consanguinity, in the second case there was no consanguinity. Dr McGillivray also showed a case of Synchronic Scintillans in one Eye in a woman aged seventy two years. Ophthalmoscopic examination revealed no further changes in either eye except slight hypermetropic astigmatism. Her defective vision was caused by well marked tobacco amblyopia. The patient seemed otherwise healthy.—A discussion ensued and the following specimens were exhibited amongst others.—A

preparation of the Decidua at the close of the First Month of Pregnancy, exhibited by Professor PATERSON, Simple Ovarian Cysts, by Dr MACFARLAN, Casts of Deformities of the Extremities, by Dr GRIGG, and a Supporting Multilocular Ovarian Tumour, by Dr KINNOCH. The President also showed the result of a recent method of Hardening Brain Substance which had proved highly satisfactory.

GLASGOW SOUTHERN MEDICAL SOCIETY—At a largely attended meeting of this Society, held on Thursday, Jan. 5th, David Couper, M.D., President, in the chair, a paper upon Diseases of the Conjunctiva was read by Dr A. MAITLAND RAMSAY, who said that out of 5828 new patients admitted to Charlotte street Eye Infirmary no fewer than 2550 or 43·7 per cent., were suffering from some conjunctival affection. After describing injuries, including burns from molten metal and from quicklime, and referring to the dermoid tumours, epithelioma and sarcoma, he spoke of the inflammatory affections of the conjunctiva. These were classified into the simple hyperemic or dry catarrhs, the hyperemic with discharge, the catarrhal and the purulent, the hyperemic with plastic formation, the croupous and the diphtheritic. He then referred to the great class of strumous inflammations—phlyctenular, pustular &c.—and concluded with a description of follicular and granular conjunctivitis. The etiology, pathology and clinical appearances presented by each of the various types were described and the principles underlying their treatment were briefly discussed. The paper which was illustrated by a large number of coloured lantern slides and by photo micrographs of various pathological conditions, was warmly received by the members of the Society.

MIDLAND MEDICAL SOCIETY—A meeting of this Society was held on Dec. 7th, 1892, Mr Enles, President, in the chair.—Mr HENRY WHITE showed for Dr Foxwell a man aged sixty five with severe Pressure Symptoms from an enlarged thyroid gland.—Dr CHRISTOPHER MANTON exhibited a Spleen removed from a case of leucocythæmia by Mr Lawson Tait. Although the extreme risk of the operation was pointed out to her the patient decided to undergo it. Mr Lawson Tait operated on Sept. 9th. The patient did not suffer in the least from shock and rallied well after the operation, but ultimately the stitch holes in the abdominal wall began to bleed and she slowly sank, dying four hours after the operation.—Mr HASLAM showed a specimen of Kidney lacerated by violence.—Dr SUOKLING then read a paper on Insomnia and its Treatment, and Mr LUCAS another on Transfusion as a means of saving Life after Severe Hemorrhage.

PLYMOUTH MEDICAL SOCIETY—Saturday, Jan 7th, was a clinical evening, Geo Jackson, F.R.C.S. (past President), in the chair.—Mr GEO JACKSON showed a smith's hammerman, aged forty three, from whose right vocal cord he had removed a papilloma with Schrotter's forceps eleven days previously. Hoarseness had been noticed for one year and seven months. Laryngoscopic examination now showed a wart on the left, nothing on the right, vocal cord. Laryngeal instruments were demonstrated and a microscopic preparation of tumour exhibited.—Mr GUGH produced a five-inch "bonnet pin" removed from the urethra of a man aged forty three. The point was felt in the perineum, cut down upon, drawn out and the beaded end extracted by slightly enlarging the wound, which healed by first intention, a catheter being tied in for three days.—Mr ROW exhibited (1) the Left Auricle of a dockyard labourer aged fifty three, removed for epithelioma (?) of the antitragus following on frost bite two years and a half previously, the mastoid gland was somewhat enlarged, (2) a Vesical Calculus weighing one drachm and a half, phosphatic crust, blood and mucus nucleus, removed by supra pubic cystotomy six weeks ago from a labourer aged forty eight years, after relief of several urethral strictures by Wheelhouse's operation four months previously. There was a sacculæ behind an enlarged prostate.—Mr THOMAS showed (1) half the Shaft of a Necrosed Fibula removed two months ago from a rickety girl aged five, and (2) Necrosed Femur from amputation of mid thigh for acute suppurative periostitis in a girl aged fifteen years, commencing eight weeks before. A huge abscess was opened five weeks before without relief. A small sequestrum was to be seen imbedded in the cancellous tissue of the lower end of the femur above the epiphysal line, and a large amount of new bone had formed at the periphery of the periosteal abscess.—Dr LUCY exhibited a Parotid Tumour removed from a farmer aged twenty four and of seven years growth. A microscopic section of a Myxo-chondro adenoma was then shown.

oxide in which have been determined by G. Krause. Vohl found sulphuretted hydrogen and hydrocyanic acid and from 0.7 to 2.8 grammes of ammonia for 100 of tobacco smoked. This investigator, jointly with Eulenberg, experimented on the smoke of strong tobacco, burnt both in pipes and in the form of cigars. The smoke was first aspirated through a solution of caustic potash and then through dilute acid. The alkali absorbed carbon dioxide, sulphuretted hydrogen, hydrocyanic, formic, acetic, propionic, butyric and valeric acids, phenol and creasote. The acid absorbed ammonia, pyridine (C_5H_5N) and all the homologues of the series to vindine, $C_{11}H_{19}N$ inclusive. In addition to the above bodies carbon monoxide, methane, and several hydrocarbons of the acetylene series were detected. Pyridine was the chief base in the smoke from pipes while collidine was the prominent base in cigar smoke. The admirable and comprehensive article on aconite bases occupies 44 pages, atropine and its allies claim 27, coca alkaloids 23, opium alkaloids 67, euphonia alkaloids 79, and tea and coffee 27 pages respectively. The sections devoted to the adulteration of tea, coffee and cocoa are as thorough as any we have seen.

Mr Allen's important contribution is doubly valuable because to a large extent it is a record of his own practical and extensive experience in analytical methods and processes. Volume III, part II, is not one whit behind its predecessors either in the able manner in which the subject is treated or in the lucidity of style characteristic of the author. It goes without saying that professional chemists, toxicologists, analysts and others interested in this study will do wisely to exercise little delay in procuring a copy of this new volume.

LIBRARY TABLE

The Hygiene of the Ear. By Professor COZZOLINO of Naples. Translated from the Fifth Italian edition by JAMES ERSKINE M.A., M.B. Glas. London: Baillière, Tindall and Cox. 1892.—In this little work of four chapters are summarised very ably the principal points of importance in the hygiene of healthy and diseased ears. The first two chapters deal with infancy and childhood. Were parents and teachers fully aware of what is written in these pages we should hear less of "stupid" children and cases of neglected discharges from the ear. The prevalence of deafness amongst school children is one of the most important subjects dealt with in this part of the work. The last two chapters are conducted on the same lines. Thus the harm that accrues to the auditory apparatus from certain drugs, sea bathing and some occupations is fully demonstrated. We are glad also to see that the author condemns the improper use of "ear-drums" and other devices so much in vogue amongst the public of this country. The last chapter concludes with an appeal for the more early recognition and treatment of ear disease. While most of what is said in this little work may be found in any good treatise on aural surgery we are strongly inclined to recommend the study of the hygiene of the ear as here set forth to those who have charge of the young. The work may be read with advantage by medical men, by school masters, and by those who have the control of large educational establishments.

Études de Clinique Chirurgicale. Année Scolaire 1890-1891. Par A. Le DENTU, Professeur de Clinique Chirurgicale à la Faculté de Médecine de Paris &c. Avec 36 figures dans le texte. Paris: G. Masson. 1892.—Professor Le Dentu states in his preface that it is his intention to follow up this volume with others, giving the results of his experience gained in the wards of the Hôpital Necker. From the character of the volume before us we hope this intention will be carried out. The first part contains a statistical account of the operations performed in this clinic for twelve months which shows the results to have been

very satisfactory and that the fruits of aseptic surgery are being reaped there. Then follows a series of twenty clinical lectures dealing with a great variety of topics, some commonplace, others rare and special. The lectures are clear and practical, and evince a high order of merit. The third part is devoted to reports of clinical cases, fifty-seven in all, observed in Professor Le Dentu's wards. They are grouped according to the tissue and parts implicated, and they are related with brevity and point. These cases are all of them noteworthy, and they are well and clearly described. The woodcuts accompanying them are in some instances poor, and ought to be improved in the subsequent volumes of the series.

Mediterranean Winter Resorts: a Practical Handbook to the Principal Health and Pleasure Resorts of the Mediterranean. By E. A. REYNOLDS BALL, F.R.G.S. Second Edition. Edward Stanford. 1892.—This is a useful and trustworthy handbook and will be found of great value to tourists and invalids. The author includes in his survey the resorts of the French and the Italian Riviera, Florence, Naples, Palermo, Catania, Málaga, Gibraltar, Corsica, Corfu, Malta, Tangier, Algiers, Cairo &c. The information given is fully up to date and remarkably accurate. The author does not write as a medical authority and always gives well known authorities for climatological statements. These will be found in the main judicious and valuable. The information regarding routes, hotels, guide books &c. is very full and correct. Within its limits this is one of the best books of the kind that has come under our notice. The only fault which we are inclined to find is with the illustrations, which are numerous and poorly executed. In future editions they should be either improved or omitted altogether.

The Queen's English up to Date. By ANGLOPHILE. London: The Literary Revision and Translation Office.—No doubt there is ample room for a book of the kind indicated by the above title, and any worthy attempt to maintain the purity of the English language, or to correct any departure from accuracy, is to be welcomed. It should be remembered, however (and this fact is suggested by a part of the title itself), that all living languages are subject to modifications, since new modes of thought and the advances of science necessitate new devices of exposition. Roughly speaking, the proper use of language is to convey exactly, in speech or in writing, the ideas it is desired to communicate to others. The law of evolution holds good in regard to language as it does for most other mundane things. Who, for example, would care to revert to the phraseology in which Chaucer couched his sublime imagery? With regard to the book under notice, whilst its object cannot but be commendable, the success with which it has been carried out may, to some minds, leave something to be desired. But who shall criticise the critics?

Recueil d'Ophthalmologie. 3e Série, 14e Année, No 10.—This part contains a case of chromatic hemianopsia by M. Galezowski, in which the patient had lost his sense of colour at about a distance of 30 on the nasal side from the point of fixation. M. Chauvel discusses phlyctenular ophthalmia and prefers in its treatment the insufflation of calomel and hot boric acid compresses. Dr. Francis Dowling contributes a paper on the influence of tobacco on vision. M. Galezowski, speaking of the symptoms and treatment of acute inflammation of the lacrimal gland, states that he had only one case in the course of ten years, 1879-1889, whilst since the visitation of influenza he has had five cases.

The A. B. C. Pocket Diary and Memorandum Book for Physicians and Pharmacists 1893. London: Burroughs, Wellcome & Co.—We have received some copies of this extremely handy pocket diary, the present edition of which will be found to be slightly improved by the addition of a calendar, postal information and a cash

the ducts, so that their excretions may the more easily be got rid of, and secondarily in some obscure way to assist the sense of touch. We would suggest that in addition they give a certain degree of roughness to the surface which enables the fingers and hand to obtain a firmer grip and retain their hold of smooth objects, but they may also, as he observes, enable the character of surfaces to be perceived by the act of rubbing them with the fingers.

Mr Galton devotes a chapter to the various modes in which a good impression of the ridges can be obtained. He describes with great minuteness the general course of the ridges, and shows how they may be divided into three main groups, which he names arches, loops and whorls, each of which presents many varieties, such as the plain arch, the tented arch, forked arch, and so on.

The persistence of these ridges is undoubtedly very great, and there are many points in the impression of each finger that can be directly and carefully compared, rendering it easy to establish the identity of the fingers making the impression after the lapse of years. Mr Galton remarks that the dimensions of the limbs and body alter in the course of growth and decay, the colour, quantity and quality of the hair, the tint and quality of the skin, the number and set of the teeth, the expression of the features, the gestures, the handwriting, even the eye colour, change after many years. There seems to be no persistence in the visible parts of the body except in these minute and hitherto too much disregarded ridges. In this work the interested observer may learn the method of studying them.

Lay Down Your Arms the Autobiography of Martha Von Tilling By BERTHA VON SUTTNER. Authorised Translation by T. HOLMES. Revised by the Authoress. London: Longmans, Green and Co. 1892.

THIS work is an autobiography of the Countess Martha Althaus, whose father was a general in the Austrian army and a keen soldier, and her two husbands were also military officers. Her first husband loses his life on the battle field, leaving her a widow at eighteen years of age with a son. Her second husband, Lieut. Colonel Baron Tilling, is ordered off to the Schleswig Holstein war, in which he takes part. Following this come rumours of the war with Prussia, which is finally declared, and he is again ordered off, together with Conrad Althaus, her sister's fiancé. The battle of Königgratz takes place, followed by the visitation of cholera at Grumitz, in which she loses her two sisters and brother, and her father dies of grief, and Conrad Althaus commits suicide on learning of the death of his future bride when he returns from the Austro-Prussian War. Baron Tilling relinquishes the service and proceeds with his wife to Paris, and is present at the siege, where, being suspected of *espionage* because a letter from Berlin is found in his possession, he is shot by the Communists. The elements of battle, murder, disease and sudden death may be consequently said to be always present and to afford opportunities for realistic and idealistic scenes. The object of the book, which is powerfully but somewhat too diffusely written, is to set forth the horrors and miseries of war and to show how terrible it is that wholesale slaughter should be the only way in which nations can settle their disputes. There is also a good deal of history and argument interspersed throughout the book. We are afraid, however, that it would be practically powerless if addressed to a nation like the French, for example, smarting under the loss of Alsace-Lorraine and willing to incur any risk in order to win back those provinces. There should be arbitration and a general disarmament, but how are they to be brought about? The terrible wholesale losses that will follow the use of modern arms in the next battle may possibly frighten any Power from going to war, or a great international society of working men may be formed in which the members bind themselves and their children not

to enter any army. The unspeakable horrors of war are generally recognised, but how to bring about a general accord among nations that it shall cease—how is that to be accomplished?

Commercial Organic Analysis By ALFRED H. ALLEN, F.I.C., F.C.S. Second Edition, Revised and Enlarged. Volume III, Part II. London: J. & A. Churchill. 1892.

CHEMISTS and especially analytical chemists have been eagerly awaiting the appearance of this volume which deals with the amines and ammonium bases, the hydrazines, the bases from coal tar and that important group of bodies, the alkaloids. It marks with singular prominence the great advances that have been made in analytical science during recent years. Ten years have elapsed since the publication of the last edition of that part of "Commercial Organic Analysis" which treated of alkaloids and tar bases. These subjects then occupied about 120 pages. In the present edition more than 570 pages have been devoted to only a part of the same subject matter, the sections on animal bases, cyanogen compounds, and proteids being reserved for separate issue in Part III. When Mr Allen undertook the task of writing a complete work on the analyses of substances belonging to the organic section of chemical science, he could hardly have anticipated the enormous labour which such an undertaking must since have entailed. In spite of this he has practically completed his task, and with admirable tact he has dealt with those peculiar difficulties which beset the completion of a work extending, as this has done, over a period during which new analytical operations have been events of almost every day. How far the facts and materials are "up to date" may be gathered from page 520, where reference is made to the adulteration of Canton tea as recently as August, 1892. Nor are the articles in the work confined to the mere description of analytical processes. Recently acquired information of the most practical and valuable kind is to be found throughout the pages of the book, embracing facts, it is true, which have already been placed on record in current scientific journals, but which have never yet been embodied in the ordinary reference manuals of the analytical chemist. This is more particularly the case with those fine products which the investigating chemist has recently placed at the disposal of pharmacy and medicine. We refer to some well-known antipyretics, febrifuges, hypnotics &c. Thus an account of antipyrin and its properties occurs on page 32, of acetanilide, or antifebrin, on page 68, of phenacetin, on page 81, of pyridine, from which many alkaloids are derived, on page 99. Many well-defined tests as to the purity of these products are for the first time described. But by far the greater part of the volume is devoted to the alkaloids, and, apart from the excellent processes which are described for their separation and the means of recognising them by an admirable series of colour tests, their history, character and constitution will probably afford still more interesting reading. A reference to the synthetic production of two distinct basic substances isomeric with quinine is a case in point. A considerable portion of the section on nicotine is devoted to the chemistry of tobacco and tobacco smoke. According to Vohl and Eulenberg the nicotine of tobacco (from 3 to 7 per cent.) is completely decomposed during the process of smoking, and the intense action of tobacco smoke on the nervous system is probably due therefore to the presence of bases of the pyridine series. The smoke from tobacco varies in character, we read, according to the proportion of air admitted during combustion, oxidation being necessarily more perfect in the case of a cigar than when the tobacco is smoked in a pipe. In the latter case a portion of the condensable products is deposited in the liquid state. Tobacco smoke, it would appear, consists in part of permanent gases, the proportions of carbon dioxide and carbon mon-

THE LANCET.

LONDON SATURDAY, JANUARY 14, 1893

ONE of the points to which the attention of the Home Secretary was especially invited by the important deputation on burial and sanitary reform which he received last week was the desirability of placing all matters relating to public health under the control of one Government Department having a Minister of Public Health as its head, and this was enforced by a quotation from a letter which Sir GEORGE BUCHANAN had addressed to Sir, SPENCER WELLS to the following effect "Pray get your colleagues to feel the idiocy of confiding to half a dozen separate Ministers the one dominant problem of securing health to the population of the United Kingdom."

The deputation urged upon the Home Secretary the grave risk to public health which is attendant on the existing methods of disposing of the dead both before and at the time of burial, and they could hardly have chosen a topic better serving than this to illustrate the evils of the present system of health government in this country. The Home Secretary has, it is true, a Burials Department in his office, but on the other hand the provision of cemeteries is now very largely a matter with which the Local Government Board are concerned. New cemeteries provided by local sanitary authorities are subject to inquiry by the latter department, who sanction loans for the purchase and preparation of the necessary land, and it is to the Local Government Board who have compiled model by laws as to the management of cemeteries that the authorities making any such by laws must go for sanction. The deputation also appealed for inquiry into the effect and influence of burial grounds and cemeteries on health, and Mr ASQUITH practically promised that such inquiry should be made by competent persons. Here again the Local Government Board have already in some measure intervened. Some few years ago a "Memorandum on the Sanitary Requirements of Cemeteries" was prepared in the Medical Department of that Board by Dr FRANKLIN PARSONS, and is now regularly issued as an authoritative document by the department. A glance at it will show that the department must already be in possession of a large amount of material such as the Home Secretary is now asked to obtain, and a staff of competent inspectors are already available to continue the work in additional directions if need be. Then again, when Mr ASQUITH was asked to deal with the question of mortuaries he had to explain that Parliament had already vested compulsory and other powers as to mortuaries in the Local Government Board, and he might have added that that Board granted loans for their erection and had issued model regulations as to their construction and management. Lastly, the deputation appealed for proper certification of the causes of death. Here Mr ASQUITH pointed out that he should have to consult the President of the Local Government Board. For any action which is needed in respect of certificates of death must be carried out by the Registrar General, who is

an official attached to that department, since amongst the matters which were transferred from the Secretary of State to the Local Government Board under the Act of 1871 was that of "Registration of Births, Deaths and Marriages." In short, the wonder is that the deputation went to the Home Secretary. The reason probably was that he being a Secretary of State, whilst the President of the Local Government Board has not that dignity, it was assumed that the comparatively trivial concern the Home Secretary had in the matters brought before him would be outweighed by his more dignified position in the Cabinet, and so long as the one subject of dealing with the dead is divided, however unequally, between two large departments of Government deputations desiring reform will doubtless select the Minister whose status gives him most influence.

The above named considerations bring us to our next point. Sir GEORGE BUCHANAN had in general terms talked of half a dozen Ministers having to do with public health. Mr ASQUITH stated that "the supervision of the public health, so far as the central government is concerned, is to all intents and purposes in the hands of two departments—I do not think more than two—this [the Home] Office and the Local Government Board." But Mr ASQUITH is in error, the control of public health matters is much more divided than he supposes. Apart from the question of burials, the Home Office and the Local Government Board both have to deal with questions affecting the housing of the working classes. One office works under one set of statutory provisions and the other office under another set. The Local Government Board have an organised staff for their inquiries, the Home Office have to call in outside help when they hold an inquiry into the subject. Another matter affecting public health is that of factories and workshops. Here, again, matters are somewhat, though less, confused. Medical officers of health have certain functions appertaining to certain workshops but the brunt of the administration is borne by the Home Office. Another example of our complicated system relates to quarantine. The Quarantine Act is administered by the Privy Council who maintain a single quarantine station and staff. If a vessel with yellow fever on board happens to run into Southampton the Privy Council deal with it under the Quarantine Acts, if it runs into Swansea they leave it to the sanitary authority to perform their duty as regards this disease much as they would as regards any other infectious ailment. On the other hand, the Local Government Board will have nothing to do with quarantine, they exert themselves to prove its uselessness and the vexatiousness of its restrictions, and they will not listen to authorities who panic stricken about cholera, plead for the renewal of detentions which have now been abandoned for some forty years in so far as that disease and this country are concerned. We come next to the new Agricultural Department. They deal with a number of diseases which affect the lower animals, such as horses, cows, pigs &c., and which also affect the human subject. Anthrax, tuberculosis, trichinosis and the like come within their purview. But all their regulations are made under statutes which are only concerned with the spread of disease among the lower animals, they do not profess even to be able to act when the milk of the affected cows produces tubercle in the human subject, and until quite

account. It shows one week on every page, has an alphabetical list for addresses, and a space for notes for 1894, notwithstanding this, its small and convenient size renders it absolutely unobtrusive in any pocket. Wallet cases suitable for holding the A B O Pocket Diary and Memorandum Book are provided at a small cost.

New Inventions.

AN IMPROVED LACRYMAL DIRECTOR AND PROBES

ALTHOUGH I think it highly undesirable to add unnecessarily to the already heavy armamentarium the ophthalmic surgeon has to support I wish to call attention to a slight modification of some lacrymal instruments which I have found useful. I have experienced, and often seen others experience, some difficulty in accurately manipulating the director which is ordinarily sold as Bowman's, because it is

too slender and does not offer sufficient bulk to be comfortably grasped by the fingers. I also have remarked that most of these instruments are too thick at the point to pass into many puncta, and have frequently found it necessary to enlarge the aperture before the director could be passed. To obviate these inconveniences I have had a handle constructed into which the proximal end of the director can be clamped whilst it is being manipulated and I have had the distal end of it made to terminate in a small button like the end of a Weber's canaliculus knife. After the canaliculus has been slit up and the lacrymal sac opened the handle can be detached and fixed to any probe which it may be considered desirable to pass, much facilitating this process by giving a better grasp and enabling the instrument to be directed with greater accuracy—a point of importance when power has to be

exerted. The probes are made of pewter and are of a con-

 bent and moulded to suit the exigencies of each case. They vary in form both as to their thickness and extremities, and are so inexpensive that with out-patients they may be left *in situ* instead of the ordinary leaden styles now so much in use. The accompanying engraving well illustrates the modified instrument, which has been manufactured for me with excellent finish by Messrs Wood and Co of York.

C S JEAFFESON, M D St. And., F R C S Edin.,
 Senior Surgeon to the Northumberland Durham and
 Newcastle Infirmary for Diseases of the Eye.

COMBINED THERMOMETER, PENCIL AND CHART TABLET

MESSRS. SALT AND SON, Birmingham, have brought under our notice a very handy little registered case containing a thermometer and a pencil with a celluloid tablet on which to record

the temperature, thus saving the necessity of separate charts. The pencil is always at hand. The case is neat, compact and well finished in aluminium bronze and will be found useful to the medical practitioner.

"IMPROVED TOILET SPONGE AND TOILET GLOVE."

MESSRS. CRESSWELL BROTHERS AND SCHMITZ, Red Lion square, London, have forwarded us two novel toilet accessories, named respectively the ablutonic loofah backed sponge and the ablutonic toilet glove. The former is a combination of an ordinary sponge and a selected piece of loofah (*Luffa Egyptica*), and is made in a variety of sizes for bath and toilet uses. This arrangement renders the loofah much more handy for purposes of friction, and as it is placed over the root, the weakest part of the sponge, its durability is prolonged. The toilet glove is made of a very soft kind of Turkey sponge on one side and loofah on the other, both sides being securely and neatly fastened together. The sponge presents a fine surface, while the loofah can be used for rubbing the skin.

Pharmacology and Therapeutics.

ANTIPIRYN IN LEAD COLIC.

MM. Devic and Chatin have found antipyrin given in quantities of sixty grains daily in divided doses very serviceable in lead colic, both in its milder and in its more severe forms. They consider it far superior to other drugs, except belladonna.

ARTIFICIAL CAMPHOR.

A French chemist—M de Mare—has devised a method of preparing camphor artificially. Camphor ($C_{10}H_{16}O$) is prepared by distilling very dry hydrochlorate of terebinthine, the product is collected in a large globe and heated, ozonised air being then introduced so as to mingle with the vapour formed. This results in a cloud of camphor ($C_{10}H_{16}O$), which becomes deposited on the internal surface of the globe. It is expected that the method will prove a great commercial success.

POISONING BY EXALGINE DISPENSED INSTEAD OF QUININE.

A somewhat novel error on the part of a pharmacist is reported in the *Gaceta Medica Municipal* of Havana by Dr Francisco Reynery. A boy two years of age, who was suffering from malarial fever, was ordered some quinine powders, one of which was to be taken every two hours. The powders dispensed, however, contained, as was afterwards discovered, five grains of exalgine. The first dose was stated to have been almost entirely vomited about half an hour after being taken, some prostration and two more attacks of vomiting followed. The second powder was given three hours after the first and produced such serious symptoms that the mother sent hastily for the practitioner in attendance informing him that the child had been poisoned. When he arrived an hour after the second powder had been given he found the child's face and hands of a dark blue tint, which was still more marked in the nails, the scrotum and the penis, the right half of the lower lip and of the tongue was black, there was copious vomiting of mucus and sweat standing on the head and the upper part of the body, the pulse could not be counted, the heart's sounds were confused, the epigastrium pulsated, and the veins of the neck were very marked, and indeed had been still more so, according to the mother's statement, the carotids were pulsating and swallowing movements were frequent, the epigastrium was tender upon pressure. The child had passed some dark grey urine containing traces of albumen. The symptoms appearing to resemble those due to acetamide the practitioner prescribed coffee and brandy, an enema containing ether, and a stimulating liniment to be rubbed over the whole body. On inquiry at the pharmacy the exact nature of the dispenser's error was discovered. Further examination showed that sensation in the lower limbs was diminished. After a few hours the discoloration had become decidedly less, the temperature, which had been a degree below normal, had become normal, the sweating was confined to the forehead, there was considerable thirst, but no more urine had been passed and there had been no more vomiting. The next day some dark urine was passed which contained a considerable amount of albumen, the colour was increased rather than diminished by heat and by the addition of an acid. The discoloration of the skin, the want of sensation and the other symptoms gradually disappeared and by the end of ten days the child was convalescent.

overtakes the female, both being 217 years, while at the age of 100 the female once more forges ahead, having a life prospect of 176 years as against 168 for the male. These figures can hardly be arbitrary or misleading and we may safely infer that the conclusion which they warrant is truly a natural law. As we have indicated, we are disposed to look for its explanation rather to the circumstances and modes of life of the two sexes than to any structural or sexual peculiarities.

The short histories of long lived persons detailed by the *Morning Post*, while interesting from the point of view of biography and anecdote, hardly warrant any scientific deductions. There are few subjects upon which more nonsense has been written than upon the means of attaining long life. The "elixir of life" delusion has had many parallels hardly less absurd. Centenarians are conscious that they are objects of general interest. They are not averse to being interviewed and they often attribute their own longevity to the most fantastic causes. A notable French centenarian not long ago ascribed his great age to the fact that he had never eaten fish. Others look for an explanation to their morning cold bath, or some trifling peculiarity of clothing or habit. It is useless to discuss such theories, which are outside the sphere of serious argument. Longevity is probably in the main a hereditary endowment and next to heredity the most potent favouring causes are probably a regular, simple and well ordered life, fresh air, plain food, temperance, and congenial occupation without drudgery.

There can be no doubt that the average duration of human life is rising steadily among civilised nations. Hygiene, medical science, the general spread of refining and moderating influences, education and the mitigation or removal of many of the plague spots of humanity share in effecting this change. Allowing for the fact that more than formerly we preserve ailing lives and prolong the duration of incurable diseases, it seems probable that, as men and women now live longer lives than formerly, they also live on the average healthier, more useful and happier lives than their forefathers.

THE meeting of Convocation of the University of London on Tuesday next will be of especial interest and importance. The members will then elect three persons and the one who has the largest number of votes will, in accordance with the usual custom, be selected by the Crown as a Fellow of the University. The existing vacancy on the Senate will, in the regular routine, be filled by a graduate in medicine or in science. Mr A. W. BENNETT, Dr W. J. COLLINS and Mr H. G. HOWSE have been put forward as candidates, and it is apparent from a glance at the lists of their respective supporters that, while Mr BENNETT will not probably be a very formidable opponent, the contest will be a very keen one between the other two. It will be decided on a very plain issue, for as both Dr COLLINS and Mr HOWSE have given evidence before the Gresham Commission, their views on the University question are well known. Dr COLLINS advocates most strongly the necessity of maintaining the existing high standard of the degrees of the University, and is a keen supporter of the policy recently approved by the majority of Convocation—namely of preserving every right and privilege now exercised by Convocation, including the right of veto,

indeed he would still further increase its power. Mr HOWSE is in sympathy with the movement for the formation of a Teaching University in London, and in May, 1891, voted for the scheme of the Senate, which would have admitted the Royal Colleges of Physicians and Surgeons to coöperation in the examination for medical degrees. In other words, whilst Dr COLLINS would still allow the existing grievance of the London medical student, in not being able to obtain a degree on similar terms to those afforded students in the provinces and in Scotland to be perpetuated, Mr HOWSE would favour some modification of the present examination system and teaching by which this injustice might be removed. Mr HOWSE is supported by a large majority of the graduates in medicine—viz., 356 against 130 on Dr COLLINS's list, omitting those who have signed both nomination papers.

In addition to the election of a Senator Convocation will be asked to approve a new scheme for the reconstitution of the University which has been recently passed by the Annual Committee. A draft report which has been circulated with the agenda at once shows that Convocation by passing the new scheme will render all compromise with external bodies impossible. It states that there must be only one University in London and that the existing University must therefore add teaching to its present functions. The teaching institutions must not be federated but coördinated under one head, and the University is not to recognise institutions as a whole, but particular teachers or courses of instruction either in the teaching institutions or outside them. Convocation is to have a representation of twelve members in a Senate of forty, to retain its present powers, rights and privileges, and to appoint at least two members on each board of studies. A Faculty of Divinity in addition to the present Faculties is to be formed. The remedy suggested for the medical grievance is simple and only needs to be mentioned—viz., the other Universities should cease to confer the M.D. degree on such easy terms, or if such degrees must be granted, they should be conferred without the necessity of residence. We commend these views to the authorities of the Scotch and provincial Universities.

For the creation of a University professorate and a staff of teachers and demonstrators the Senate is to have power to appoint members of the teaching staffs of the Colleges or other higher educational institutions as University professors, teachers and demonstrators, with endowments from the funds of the University (which are apparently expected to come from the City Corporation and the London County Council), on condition that the appointment to such chairs, whenever a vacancy occurs should pass to the University. The Teaching Colleges and the Medical Schools are therefore expected to give up their autonomy, whilst certain of their lecturers and teachers are to be formed into a select class and to be labeled by the Senate of the University as University teachers in medicine, surgery &c., and in the various branches of arts and science, and these appointments are practically to be made irrespective of the governing bodies of the schools and colleges. Such a scheme shows a hardy belief in the capacity for greater developments on the part of a reformed Senate, in which Convocation will have increased power, but it is scarcely likely to be seriously considered by those who are now responsible for the efficiency and work of the Teaching Colleges and of the Medical Schools.

recently, when a new order as to anthrax was issued, they did not even require their staff to inform the health officer of the existence in a given locality of a disease so fatal to man as anthrax. But the moment a man contracts one or other of these diseases—in fact, when the mischief which ought to be avoided has already been brought about—then the Local Government Board is appealed to, and our readers must have seen how almost hopeless has been the task of prevention in numberless outbreaks owing to the confused functions of the two departments. Well may the deputation appeal for unity in the administration of laws affecting the public health.

We do not here discuss in any detail the actual proposal as to a Ministry of Health. Mr ASQUITH, asked to advocate unification of departments, only replied that he objected to their multiplication. Here politicians and administrators will agree with him. New departments start well, but their status is not always maintained. The first Minister of Agriculture was in the Cabinet, but the next one found no place there. A new Minister could hardly be accorded the status of a Secretary of State, whereas public health considerations are becoming so important that the Minister responsible for them ought to have such rank. For this reason alone it has been suggested as a better and a more feasible scheme that the Home Office, which is now but little more than a Ministry of Justice, should be made such in reality, and that the subordinate functions it performs as to burials and housing of the poor, as also those relating to factories and workshops, should be handed over to the Local Government Board as a Ministry of the Interior, and that the chief of this Department should be a Secretary of State. Quarantine functions would naturally be swept into the same net in order to be abolished, and some very necessary changes could be made as to dealing with the diseases of animals which have any bearing on the health of man. We do not profess to indicate now which is the better administrative method, but would advise our readers to consider carefully both schemes and to judge which would be most likely to lead to the desired end and which would stand the best chance of being carried into effect.

OUR contemporary the *Morning Post* has taken the trouble of tabulating all the cases of exceptionally long life recorded in its obituary columns during the past year and of giving such particulars as are available regarding the various centenarians included in the list. It is not to be expected that results drawn from an exceptional and limited field should possess any high scientific importance, but the facts recorded possess considerable interest and may suggest some reflections not without value. In dealing with such facts we are always beset with the difficulty of deciding whether some apparent conclusion is really a natural law or only an erroneous generalisation which would be corrected by a wider induction. Thus, when we find that the percentage of those who attained the age of eighty and upwards was only 6.7 in 1892 as compared with 16.6 in 1891, 12.6 in 1890, and 15.5 in 1889, it would be very rash to conclude that there was any general decline of longevity. No doubt, this low figure is an accidental fluctuation and requires to be read in the light of the averages of a long series of years.

The octogenarians recorded in these tables numbered 1151, and it is found that of these 505 were males and 646 females. It appears, also, that at all ages above eighty, with perhaps a casual exception or two, the proportion of long lived females exceeds that of long lived males. Thus, 63 women died in their eighty first year, as compared with 60 men, 75 women died in their eighty third year, as compared with 63 men, 48 women died in their eighty sixth year, as compared with 34 men, 26 women died in their ninety first year, as compared with 17 men, 5 women exceeded the limit of 100 years, as compared with one man. A ratio so steadily maintained as this must possess some significance, even making every deduction for the limited nature of the data, and we are naturally inclined to seek for some explanation. We are disposed to find the explanation, not in any sexual peculiarity, but rather in the different circumstances which characterise the lives of elderly men and elderly women. While there are many exceptions, there can be no doubt that on the whole women lead easier lives than men. Their occupations, however harassing and engrossing, are still in the main much less laborious than those of men, and, in addition, women are as a class largely removed from many of the gravest perils which shorten the lives of men in various occupations. The army, the navy, the mercantile marine and a majority of the most noxious trades employ men only, and it may be said that there is hardly any single occupation of exceptional risk which is carried on exclusively by women. Sick nursing, which might be thought to be an exception, is, on the whole when properly organised, a healthy occupation, the regularity of life and habit, the knowledge possessed by the trained nurse and the high *morale* required of her more than compensating for the risks arising from frequent contact with infectious disease. Women, especially when they are advanced in years, are largely removed from conditions which imperil longevity in men. A woman over seventy who still works laboriously for her living is fortunately an exception, whereas most men, even when there is no absolute necessity, dislike the idea of retirement and inaction, and work on preferring to die in harness.

The influence of sex upon the duration and prospect of life is an interesting subject upon which we possess a good deal of information. As is well known, the proportion of male births definitely exceeds that of female births in the proportion of 30 or 40 per 1000. The mortality of males in early life exceeds that of females, while in middle life the perils incidental to child bearing swell the rate of female mortality. In advanced years again, as we have seen the expectation of life is decidedly somewhat better in the female. Dr OGLE, in the life table compiled from the mortality returns of the years 1871–80, shows that at birth the expectation of life is 41.35 years in the male as compared with 44.62 in the female. At each succeeding point the female average keeps steadily ahead. Thus, at five years of age a boy may hope for 50.87 years of life, while a girl may hope for 53.08, at the age of ten the respective prospects are 47.60 for the male and 49.76 for the female, at the age of twenty the figures are 39.40 and 41.66 respectively, at thirty they are 32.10 and 34.41, at fifty 18.93 and 20.68, at seventy 8.27 and 8.95. Curiously enough, at the age of ninety five the male average

ALMONERS

THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON

THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL

THOMAS WAKLEY, F.R.C.S. Eng

THOMAS WAKLEY, Jun., L.R.C.P. Lond.

HON AUDITOR

SIR HENRY PITMAN, M.D. Camb, F.R.C.P.

— o —

THIS FUND will be provided year by year in the month of January to the amount of at least £300 solely by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to Medical Men, or their Widows and Orphans, in cases of Distress and Emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require

Applicants must satisfy the Almoners of the Fund that they are qualified under the following regulation —

- * "The recipients shall be such persons as satisfy the Almoners that they possess one or other of the following qualifications—that is to say (a) That the applicant holds some registrable medical qualification, and that he has fallen into pressing need of immediate pecuniary relief, or (b) That they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registrable medical qualification, and that they have pressing need of immediate pecuniary relief "

To ensure the utmost despatch, the "Application Form" upon the other side should be filled up and forwarded (in an envelope superscribed "THE LANCET Relief Fund") to the Secretary, Mr EDWARD DAVIES, THE LANCET Offices, Strand, London, W C !

The application should be accompanied by two separate testimonials, one from the Clergyman of the Parish or other resident Minister of religion, and one from a registered Medical Practitioner, stating—that the application addressed to the Almoners has been read, how long they have known the applicant, and that they believe the statement to be perfectly truthful, and such as may be acted upon without further inquiry

Annotations.

"Ne quid nimis."

ALLEGATIONS AGAINST HOSPITALS

THE first two weeks of this year have been marked by the appearance of an unusual number of complaints against hospitals, and we feel compelled to again strongly record our protest against the manner in which they are brought forward and the undue prominence which is given to them. The art of magnifying trifles must be of great value to the newspaper man who has a sensation to work up. Moreover, it is always possible to strike at a hospital by bringing charges against it, for should the charges be false the hospital has no remedy. It is safe to hit those who cannot strike back. Newspapers should avoid saying anything likely to damage institutions which exist only for the benefit of the sick poor, but should rather use every effort to help and protect them. The Poplar Hospital for Accidents has recently been attacked and the ultimate result of the inquiry has been to clear the authorities of all blame. The termination of the inquest at which the charges were brought forward was marked by an unusual incident, the coroner himself gave five guineas to the funds of the hospital, thus marking in the most public manner his appreciation of the benefits conferred by the institution on the poor of the district in which it is situated. This hospital, dependent on voluntary contributions and located in a poor neighbourhood, cannot afford to have charges, however unsubstantiated, brought against it, for they result in loss of income and therefore loss of efficiency. The income is already inadequate, but the utmost possible is done with what is available, and there are few institutions more deserving of support. There are three things in connexion with hospitals that it is difficult to make the public understand—one of these is the fact that without funds the number of beds cannot be kept up, and some one must therefore occasionally be sent away because there is no room, another is that the management of the hospital must be left in the hands of those responsible for it, whose duty it clearly is to act for the good of the largest number, and the third is that the parish (and not the hospital) is responsible for the sick poor living in it. When the treatment required by any particular patient can be carried on equally well at home or elsewhere hospital authorities are quite right in sending away such a patient—provided it can be done without risk—in order to make way for another to whom the special care of the hospital may mean rescue from death. There has been some talk of the formation of a society for the protection of hospital patients, the person with whom the idea (what an idea!) originated would find plenty of employment for his surplus energy if he were to form a society for the protection of the institutions which exist simply for the benefit of the poor. Perhaps if the newspapers at fault in bringing forward these allegations were really compelled to apologise the apology would only be gracelessly rendered, as a memorable excuse for similar conduct was once given—"When you have to get up a sensation daily you must make a mistake sometimes." But even the best apology could seldom make amends for the harm done. "Save me from my friends!" may well be the cry of the poor man.

YEARLY RECORDS OF THE PROFESSION

THE advent of a New Year is marked in the medical profession by the appearance of a new Medical Directory¹ and, more tardily of necessity, of the Medical Register for the

year. It is a common custom with us to analyse the principal statistics of the profession and its growth as illustrated in the columns and tables of the Medical Register. This, indeed, is the authentic roll of the registered practitioners of this country and its dependencies and for this and other reasons is invaluable. But we must wait some months for this important book, and meantime we are fain to study the one which comes first to hand and which, indeed, makes a creditably prompt appearance in the first week of the year. It is noticeable that these separate and perfectly independent lists of practitioners do not altogether agree as to the numbers of the profession. Thus for the year 1892 the Directory gave as the numerical summary of the profession 30,035 while the Medical Register of the same year gave 29,555, being a difference of 480. There are other differences in the works which give to each its peculiar value. In the Register the whole profession is given in a continuous alphabetical list, while in the Directory it is divided very conveniently for the reader into a section for London, the Provinces, Scotland and Ireland respectively, for Practitioners Registered Abroad and for those in the Naval, Military and Indian medical services (excluding those which appear in other lists). There is a startling feature in the summary of practitioners for the year as given in the new Directory—viz., an increase in the numbers for the year of no less than 724. Thus in 1892 there were 30,035, in 1893 30,759. In Ireland the increase in the number of practitioners is only 5, from 2445 to 2450, in Scotland it is 124, from 2850 to 2974, in the provinces 377, from 14,026 to 14,403, in London 114 from 5293 to 5407. We shall wait anxiously for the Register to see how far it supports this representation of an addition in one year of 724 to an already overstocked profession. The publishers of the Medical Directory issue a circular yearly to every practitioner for the data of his description, failing a reply, they insert his name, but indicate that no return has been made by an asterisk, which denotes uncertainty as to the facts. These asterisks are in some pages pretty numerous, amounting sometimes to about 13 per cent and sometimes to about 18 per cent, as we find by a cursory glance. Another source of possible error is the non elimination of deceased members of the profession, but, after making all possible deductions, it must be admitted that there is an ominous growth in the numbers of the profession, out of proportion to the growth of the population or of its needs. But the figures respecting the numerical strength of the profession are only a small part of the interesting information with which this volume abounds and which makes it an indispensable element in the library of a medical man. It must be admitted that its description of a medical man and his status is more complete than could possibly be given in a Register which is restricted by Act of Parliament. Not only are a practitioner's qualifications given, but the schools at which he has studied, the appointments he holds, the societies with which he is connected and his contributions to the literature of the profession are noted. A very valuable feature of the Directory is the Local List which precedes the List of Names both in London and the provinces. It is interesting to notice that of the whole number of medical practitioners 5502 are engaged abroad or in the Naval, Military and Indian services. It would take too long to enumerate the various sections of the Directory devoted to abstracts of chief Medical Acts, the medical schools of the three divisions of the kingdom, the Sanitary Medical Service, the Local Government Medical Service, and the hospitals, dispensaries and lunatic asylums of the various counties. It is interesting to notice that the obituary list of the profession given in this volume, purporting to be the deaths from November, 1891 to 1892, amounts to 631 deaths. This number very closely corresponds with the numbers generally given in the Medical Register. The Registrar, it is known

THIS FUND will be provided year by year in the month of January to the amount of at least £300 solely by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to Medical Men, or their Widows and Orphans, in cases of Distress and Emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require

Applicants must satisfy the Almoners of the Fund that they are qualified under the following regulation —

- * "The recipients shall be such persons as satisfy the Almoners that they possess one or other of the following qualifications—that is to say (a) That the applicant holds some registrable medical qualification, and that he has fallen into pressing need of immediate pecuniary relief, or (b) That they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registrable medical qualification, and that they have pressing need of immediate pecuniary relief "

To ensure the utmost despatch, the "Application Form" upon the other side should be filled up and forwarded (in an envelope superscribed "THE LANCET Relief Fund") to the Secretary, Mr EDWARD DAVIES, THE LANCET Offices, Strand, London, W C !

The application should be accompanied by two separate testimonials, one from the Clergyman of the Parish or other resident Minister of religion, and one from a registered Medical Practitioner, stating—that the application addressed to the Almoners has been read, how long they have known the applicant, and that they believe the statement to be perfectly truthful, and such as may be acted upon without further inquiry

Private and Confidential

No

APPLICATION FORM

To the Almoners of the Lancet Relief Fund

The applicant should here state shortly —

1 The nature of the emergency that has arisen

2. The circumstances out of which it has arisen

3. The amount of the grant desired, and whether by way of loan (free of interest) or of gift.

4. If by way of loan, state when the loan will be repaid, and from what source the funds to repay it are expected to be forthcoming

5 Whether the applicant is entitled or able in the circumstances which have arisen to look to any other source for assistance, and if so, what is the expected nature and extent of such assistance

6 Whether the applicant is receiving, or has received during the past six months, pecuniary aid from any Medical Charity

7 State how the applicant is qualified to receive assistance, vide regulation* on first page.

8. Particulars of

takes advantage of all means for ascertaining the death of every medical man, and in the Register for 1892 gives 581 as the deaths for 1891. For the last sixteen years the average of deaths annually has been 570. For the last five years the average is 529. In four years only has the number exceeded 600. It speaks much for the care with which this information is gathered that it brings the list up to the highest possible figure. As our readers are aware the gaps made by death are always more than filled by the plentiful additions to the profession. In the year 1891 no less than 1345 were added. This does not diminish the pain with which many of the losses have to be recorded, but it relieves the national mind of the fear of any scarcity in the supply of healers.

THE SPREAD OF SMALL-POX

TEN years have elapsed since the Royal Commission on Small pox and Fever Hospitals reported that "it is evidently of paramount importance that the areas of the small pox wards as well as their administration should be rigorously separated from those of the fever hospitals, and, further, that their construction should be such as to reduce within the smallest limits the chance of spreading infection." Since then we have repeatedly had instances of the spread of small pox from buildings in which cases of that disease have been aggregated. When Warrington attempted it recently the patients professedly under isolation in other pavilions contracted small pox, and now we learn that in Leicester the same thing has taken place. No less than fifteen scarlet fever patients contracted small pox in a so called isolation hospital and the scarlet fever wards had to be closed. The time has surely arrived for adopting some reasonable action as to the isolation of small pox in the provinces, for the disease is still extending in many parts of England. Last week brings news of three fresh cases at Batley, three at Dewsbury, three at Bootle, five at Chadderton, seven at Oldham, seven at Barnsley, four at Rotherham, five at Huddersfield, four at York, six at Leicester, three at Southampton (the outbreak at which place is more fully dealt with elsewhere) twenty one at Manchester three at Wakefield, and there have also been smaller outbreaks at Bradford, Halifax, Birkenhead, Liverpool, Lancaster, Birmingham, Derby, Darlington, Swansea, Bakerswell, Bedale, Durham, Castle-Bytham, Louth, Pontefract, Runcorn and Denaby Main. Nine cases are now under treatment in the last-named place.

DECAYING HUMANITY IN OUR CHURCHES

A letter appeared in *The Times* some days ago from Major Joseph, the churchwarden of St. Antholin's parish for upwards of twenty years. In it he describes his action as regards the bodies interred in the vaults of the church at the time of the removal of the building. He found upwards of six hundred coffins, nearly every one of which was in precisely the same state as those described as being in the churches of St. Mary Woolnoth and St. Mary at Hill. "I placed," he proceeds, "every coffin in a new outer shell, and instead of going to the expense of removing them to Ilford I enlarged the rector's vault at the end of the church and there deposited the coffins, making a register of such. The work was performed under the superintendence of the late Dr. Tidy and Dr. Sedgwick Saunders, under whose orders large quantities of carbolic acid were used and a small ration of rum was served every two hours to the workmen employed. We had no case of sickness and neither the public nor the friends of the deceased were in any way shocked. I write this in the hope that you may be able to spare space for its insertion and that it may be useful to the churchwardens of the two before-named parishes and be the means of saving outlay to the parishioners." While giving every credit to Major Joseph

for this economical mode of meeting a serious difficulty we must express a preference for the entire removal of human remains from the heart of the City to some suburban cemetery. As a matter of fact, some such experiment as he made so successfully was tried in one of the churches to which he refers, with the result of making matters worse instead of better. Burial in the earth, not entombment, must be considered as the order of the day, subject to the searching inquiry which will probably soon have to be made into the whole matter.

APPOINTMENTS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD

SOME delay is being occasioned in the final selection of inspectors by which the Medical Department of the Local Government Board is to be reinforced in view of the increased duties which will be involved in consequence of the prospects of cholera during the current year. But we understand that three of the intended appointments have now been made for a period of one calendar year. The gentlemen thus appointed are Mr. Evan Evans, D.P.H., now assisting in the health department of Bethnal Green, Dr. Thomas Horne, formerly medical officer of health for Sandwich, and Dr. Hector McLean Wilson, assistant medical officer of health for Leeds.

UNQUALIFIED PRACTITIONERS IN HULL

THE deputy coroner for Hull made some strong and proper observations a few days ago in commenting on the case of a child four years and a half old, which had been taken by its parents to the surgery of Dr. Haynes, but was attended by Mr. E. H. Knight without authority or qualification to practise medicine. He was not even an assistant to a qualified practitioner, but used that surgery two years and a half after Dr. Haynes had left it in such a way as to mislead the public. The deputy coroner made an important point in his remarks. We are apt to think that it is only by the false use of titles specified in the Medical Act that the public is misled, but the word "surgery" on a sign or a brass plate is as misleading as the word "surgeon", and the coroner expressed himself greatly astonished that there should be in a populous street a gentleman who had a sign above his door which led persons to believe that the premises were tenanted and used as a surgery while they were occupied by a totally unqualified man.

IMPORTANT PROSECUTION UNDER THE MARGARINE ACT

THE chief sanitary inspector of Wigan, who is also inspector under the Food and Drugs Adulteration Act, has been remarkably active since his appointment. Quite recently he was the means of bringing to justice a tradesman in that town for exposing margarine as butter, the magistrates convicted and fined the defendant £20 and costs. Now he has had a much more important case—a gross case of fraud on the public, poor and rich. A woman dressed as a respectable farmer's wife was accustomed to attend the Wigan market on the most important market day—namely, Friday—and beside her stall of cheese and eggs she had a basket containing what she sold as butter in prints. He asked her what was in the basket and she said butter. He asked to see it and she picked it up and uncovered it, and it contained "prints" of one pound, this being a form in which butter is put up by farmers for sale. The inspector then wanted to buy some for analysis and thereupon the defendant said the basket did not belong to her, and that a woman had left it with her that morning. She could give no information regarding this woman. The inspector took charge of the basket. Two pieces of this so-

called butter were submitted to Dr Campbell Brown of Liverpool, and his certificate proved that one piece contained 10 per cent of water and 90 per cent of fats other than butter, and that the other contained 10 per cent of water and 82 per cent of fats foreign to butter. The town clerk, who prosecuted, described the case as one of the "very worst kind," the very nature of things leading the purchaser to believe that he was buying fresh butter. Mr Roocroft, the presiding magistrate, said the Bench thought it was as bad a case as could possibly be brought before them. The defendant came apparently from the country to the market-place, where fresh produce was expected to be sold, and the unsuspecting public would naturally think she was a respectable farmer's wife and that the articles she was exposing for sale were of the purest possible character. The defendant was fined £5 and costs. After paying the fine the defendant claimed the basket and the "stuff" it contained.

INFLUENZA

CASES of influenza are reported from various parts of the country. For example, in the West Riding of Yorkshire the county medical officer's return gives intimation of cases being notified to him from 31 sanitary districts (out of 160), which returns were received in the month of December. The summary of the past six months shows that in no month has it been entirely absent from the West Riding. A correspondent at Bedford writes that there have been "numerous cases of influenza in this town since the beginning of October. The type, on the whole, has been mild, so that the majority of cases have not been seen during the attack, but have come under observation for some complication or sequela. There have, however, been a few severe cases of pneumonia in children, evidently following a neglected attack of influenza." Similar testimony reaches us from Somersetshire, and cases are doubtless fairly distributed throughout the country. Nevertheless there is nothing at all approaching the visitation of the past year, nor is it likely to become so severe and extensive again for a generation. That influenza persists in some localities for long periods, or recurs at short intervals, is recognised by authorities, but its pandemic outbursts are relatively infrequent.

NEW YEAR'S CUSTOMS

IN Lancashire and probably in other counties in England, it is a general custom for tradespeople to give their customers Christmas and new year's "glasses," this custom extending even to letter carriers, policemen, carters and carriers in some villages. It is a most vicious custom and causes at times many unpleasant reminiscences. In towns the giving of drink to postmen and policemen is dying out, probably owing to the fact of the authorities discouraging it, with tradespeople and their customers it still exists. A most painful case of this sort occurred this year at Golborne, a village in Lancashire, near Newton-le-Willows. The subject of it became the cause of a coroner's inquiry. He was a single man nineteen years of age, living in lodgings and had only just arrived from Ireland. It appears that he was "keeping up" new year's day with some companions, and in the evening they adjourned to a well known public house, where a carousal took place. Other public houses were visited, the landlords giving what is termed "the new year's glass." In all, it is said, this boy—he can scarcely be called anything else—had drunk up to half past nine at night fifteen or sixteen glasses of rum. He then became so stupefied that he had to be carried to his lodgings in a helpless state. His condition getting worse, a medical practitioner was sent for, who used every effort to counteract the effects of the alcohol, but without effect, for the patient died at 2 A.M. on the next day. The verdict of the coroner's jury was to the effect that the deceased died from alcoholic poisoning, adding that they

exonerated the landlord from blame. It certainly would have been better if medical evidence had been called at the inquest, in fact, a case of such importance should have been one for a post-mortem examination and medical opinion, for notwithstanding the alcoholic intoxication other causes of death may have existed.

SPURIOUS VACCINATION IN BELGIUM

AT a recent meeting of the Belgian Medical Federation Dr Wibro gave an account of a strange kind of vaccination in vogue amongst the inhabitants of certain villages. The child is "vaccinated" in the usual situation with a needle which is charged by being previously inserted into one of the pustules which occur in pigeons in summer, which are vulgarly looked upon as small pox pustules, but which are in reality produced by mosquito bites. Of course, this vaccination is absolutely useless as a prophylactic against small pox, but it gives rise to cicatrices which at first sight may be readily mistaken for those of true vaccination. The false scars are, however, distinguishable from the true by being quite flat and not swollen or raised. They resemble, in fact, the scars following very superficial ulcers.

THE JOHNS HOPKINS UNIVERSITY (BALTIMORE) MEDICAL FACULTY

THE full organisation of this school has been delayed owing to the lack of necessary funds, but recently Miss Mary Garrett of Baltimore has given \$300,000 which makes up a sum of half a million dollars now in the hands of the trustees for the completion of the school. The biological, chemical and pathological departments have been organised for some years, under the charge of Professors Martin, Rensen and Welch. Three years ago, when the Johns Hopkins Hospital was opened, the medical, surgical and gynecological departments were placed respectively in the hands of Professors Osler, Halsted and Kelly. The chairs of anatomy and pharmacology are not yet filled. The curriculum suggested in the preliminary announcement will consist of a three years' science course (or its equivalent) and a four years' medical curriculum. The preliminary medical course of the Johns Hopkins University, which has already been a very popular one for medical students of the better class consists, in the first year, of physics, chemistry, English, history and physical geography, in the second year, biology, chemistry and German, in the third year biology, French, psychology, logic and ethics. Students who have passed French or German as a principal subject in place of Greek for the matriculation must substitute some other subject, such as Latin or mathematics.

FOOT-AND-MOUTH DISEASE IN CATTLE

THE sudden appearance of foot-and-mouth disease in a dairy at Barnsbury, North London, on Jan 1st has been a startling surprise and has caused much alarm and wonder. Its introduction is even more mysterious than the invasion of last year, the source of which was never satisfactorily traced, though it was ascribed but without reliable evidence, to imported cattle from Denmark. In the Barnsbury outbreak there is nothing whatever to fall back upon to account for its advent, none of the nine animals in the cowshed having been near any infected cattle or in any place where they could be contaminated for a much longer time than that of the period of incubation of the disease, consequently all kinds of surmises have been promulgated as to the origin of the malady, the most plausible of which perhaps is that the infection has been conveyed to them by some intermediate vehicle, such as litter or forage. But this is a mere suspicion, for which there is probably as little foundation as for any of the other hypotheses started to account for the unfortunate occurrence. As usual the spontaneous development theory has been

brought forward in response to the desire for information as to the outbreak, and an attempt has been made to prove that insanitary conditions will produce this and other infectious and contagious diseases of the domestic animals. This of course is a grave and dangerous notion which should at once be dispelled. Everyday experience, as well as the entire history of these communicable disorders, demonstrates that they cannot develop spontaneously, and that their existence and extension depend upon their virulent properties. Once destroy the virus which generates them and they are seen no more. The evidence in support of this statement is also lately overwhelming. No doubt insanitary conditions of dwellings and bad or improper food and management may predispose animals to the ready reception of the virulent agent, but without these disorders will not appear. And it must not be forgotten that animals living in the open air, on wide plains, suffer from such diseases and sometimes most severely. Just now foot-and-mouth disease is causing great apprehension because of its rapid advance in South Africa, where the immense herds and flocks are never housed, and in the same region, as well as in our Australian colonies, contagious pleuro-pneumonia of bovines has proved a ventable scourge among the roaming herds. By all means let the sanitary condition of animals in the United Kingdom be improved, but let us also stamp out the virulent principle of contagious diseases and prevent its introduction from countries beyond our sea boundary.

DIPHTHERIA, SCARLET FEVER AND MEASLES IN THE CHELMSFORD DISTRICT

For the past three months an extensive epidemic of measles throughout the Chelmsford and Maldon Rural Sanitary Districts has prevailed, and a considerable number of schools have had to be closed for this reason. In certain parishes complications have arisen on account of the prevalence of diphtheria and scarlet fever also. In the village of Stock, during an epidemic of measles, a case of scarlet fever and diphtheria was introduced, and by the agency of the schools the latter diseases spread amongst the children. Unfortunately the scarlet fever was not at first recognised and children from infected families continued to attend school until they were closed on Nov 1st. Since then about forty cases of diphtheria have occurred, in several instances complicated with scarlet fever and in others with measles, and there is reason to believe that in one or two cases the patients had all three diseases for all three were prevalent in certain families at the same time. Dr Thresh is about to issue a detailed report of this interesting outbreak. Fortunately only two deaths have resulted from diphtheria and one from scarlet fever (in Stock) and no fresh house has been attacked during the past month.

THE YERBURY-ROAD SCHOOLS

THE magistrate of the Clerkenwell Police-court Mr Horace Smith, after hearing the evidence on both sides as to the drainage of these schools and having paid a visit to them for the purpose of personal inspection, has given an order for the changes and repairs required by the vestry of Islington. It is to be regretted that this order was necessary and that the board should have resisted the wishes of the vestry. It will be noticed that the vestry, through its officers did not commit itself to any dogmatic assertion as to the connexion of the leaking and almost horizontally laid pipes with the causation, or even with the prevalence of diphtheria in the schools and Mr Smith wisely intimated from the first that he would not go into this question. He restricted himself to the question of the efficiency and soundness of the drains, and even on the admissions of the officers of the School Board only one conclusion was possible to a magistrate. It is perhaps

impossible to prevent schools becoming the medium for circulating a great deal of disease, but this evil must be reduced to a minimum. Certainly coarse structural defects must be remedied and drainage must be above suspicion. While we regret the collision of the medical officers of the School Board and the vestry, we cannot regret that this battle has been fairly fought out in open court. It will tend to prevent such collisions in future, and it will perhaps also tend to enlighten the public as to the limited power of public bodies like the School Board to control building operations. The public seems inclined just now to impose on such bodies, made up for the most part of men busily engaged in private affairs, an indefinite amount of work. If this is not checked and the work of public bodies somewhat proportioned to the leisure and the ability of their members great public evils must result.

EFFECT OF CHLOROFORM ON LABOUR

THE exact effect of chloroform inhalation on the contractions of the uterus during parturition has been recently experimentally investigated by Dr Dönhoff in the Kiel Obstetric Clinic by means of an india rubber bag passed into the uterus, communicating with a recording manometer, a kymograph and a mercurial manometer by means of a tube which, together with the india rubber bag, was partially filled with water. He finds that a slight degree of chloroform narcosis has a paralyzing effect on the uterine contractions, the pressure falling to nearly half what it was previously. If the chloroform is stopped the pressure during a pain increases, but at first to only about two-thirds of the original pressure. In two of the cases observed the initial pressure was not regained until two hours after the cessation of the administration of chloroform. In cases where the abdominal muscles assisted the uterine contractions to only a moderate extent this auxiliary was entirely arrested by chloroform even when the patient was only partially under its influence, but when the muscles exerted a great deal of force their action did not entirely cease unless the patient was fully narcotised. The intervals between the pains were prolonged by chloroform, so that when the patient was partially anaesthetised the number of pains in a given time was diminished by 20 or 25 per cent.

SURGEON-MAJOR KING, I.M.S.

MUCH indignation appears to exist in India at the treatment to which Surgeon Major King has been subjected by being transferred from civil to military duty by an order of the Government of Madras to that effect, which has since been confirmed by the Government of India. It seems that Surgeon Major King made certain experiments by which he was able to prove that small pox virus obtained from the vesicles of a patient suffering from that disease produced cow pox attended with some constitutional symptoms and a rise in temperature, in healthy calves when inoculated therewith; and further that, by the aid of lanoline, vaccine lymph can be kept in a good and efficacious condition for months whereas it has been found difficult in India to preserve the vaccine lymph under other methods. The scientific interest and practical value of these observations cannot be doubted, and most persons would consider their author entitled to great credit. As far as the results of Surgeon Major King's experiments went to establish that small pox virus in the human subject gave rise to cow pox in calves they have been since corroborated by experiments undertaken in this country by Dr Hime. But it appears that with full faith in the safety of the experiment as the symptoms in the calf were absolutely characteristic, Surgeon Major King forwarded some of the preserved vaccine lymph thus obtained to a medical officer at Anantapur for trial, and no harm resulted from this in any way as far

as we can gather The Government of India, endorsing the action of the Government of Madras, holds, however, that his conduct in instituting and conducting his experiments and in disseminating lymph prepared from small pox virus without the express permission of the Madras Government was irregular and indiscreet and might have had the result of provoking hostility to vaccination and perhaps to the Government under which he was serving Surgeon Major King was consequently deprived of his civil appointment and relegated to military duty at Mandalay Allowing that this officer's action was technically, and in an official sense, wrong, still we think that the reasons given by the Government of India are far fetched and exaggerate its importance There is nothing to indicate that it was not the result of sheer inadvertence and professional zeal, for his demonstration that cow pox is nothing but small pox modified by having passed through the cow's body was an important one, which, as we have already said, was subsequently confirmed by Dr Hime Surgeon Major King can appeal, no doubt, to the Secretary of State and get some persons of influence in this country to take up his case, but we trust that this will not be necessary and that the Government of India will recognise that they have already gone far enough and virtually cancel their decision in the matter by restoring this officer to civil employ

THE EFFECTS OF THE CANAL BOAT ACTS

It is characteristic of modern legislation that it is becoming increasingly concerned with the settlement of social questions The main principles of human conduct and the rights of property are no longer its only or even its chief objects, but many other matters of less immediate importance in the nation making ages of the world have latterly provided it with worthy occupation Such, for example, is that of which we have been reminded by the last annual report of Mr Brydone, the chief inspector under the Canal Boat Acts for England and Wales Notwithstanding the revelation of not a few discouraging facts, the pages of this report furnish abundant proof of the good work effectively done for health and education by the administration of these Acts Cleanliness has increased, overcrowding, though still much too prevalent and, in the circumstances, by no means easy of cure, has undergone marked reduction, the work of education has made evident progress in spite of the difficulty interposed by a wandering life, and the spread of disease has been limited by the notification of infectious diseases It is further satisfactory to note that these desirable objects have been attained with comparatively little friction of temper, thanks to the judicious conduct of the official inspectors The mental and moral character of the barge population has improved in proportion to these beneficial changes in their vital conditions and we shall, on the whole, be fully justified in saying that experience has proved the practical value of measures in which the spirit of humanity has leavened with such good effect the hard legality of simple justice.

THE LEPROSY HOSPITAL NEAR DRONTHEIM

A DESCRIPTION of a visit to the Leper Hospital near Drontheim in Norway formed the subject of a paper recently read to a Hesse medical society by Dr Kunze The disease, according to his view, is most probably connected with fish-eating as it is most rife amongst the fisher folk and the dwellers near the sea coast in Spain, Russia, Norway and Sweden The hospital is built on a high barren table land about half an hour's drive from Drontheim It is absolutely isolated, there being no habitations within sight It is a long barrack like two storeyed building with two wings and a third building at right angles to the main part It is kept spotlessly clean. The kitchens are underground. The

male and female departments are of course separate The total number of patients is between two and three hundred, a great many of them being in the prime of life Their general appearance is distressing, most of them being pale and thin, with sores or recently healed scars on their faces, which at first sight might be mistaken for the effects of lupus In many cases the nose or lip is completely eroded, so as to expose the bone In about 20 per cent. of the patients the eyes are affected and in from 40 to 60 per cent. the hands and forearms, many having lost one or more fingers

SCIENTIFIC EXPEDITION TO SIAM

DR. YERSIN, formerly an assistant in the Pasteur Institute in Paris, has been sent by the French Government on a scientific expedition to investigate the region between the Don Nai and the Mekong as well as the table lands in Siam between the Mekong and Bangkok.

ROYAL MEDICAL BENEVOLENT COLLEGE

WE have pleasure in announcing that Sir James Paget has consented to fill the office of consulting surgeon to the Royal Medical Benevolent College in the place of the late Mr Cock, who had been connected with the institution for so many years The disinfection of the buildings after the epidemic of scarlet fever which was imported into the College last term is being carefully carried out with the advice and under the supervision of the medical officer of the College, the surveyor of the local board of health and the medical officer of health for the district This is as it should be.

HÆMORRHAGES IN THE NEWBORN

IN the *Centralblatt für Bakteriologie und Parasitenkrankheiten*, xii, 17, 1892, Drs Trüvel and Quervain report two cases of hæmorrhages occurring in the new born in which bacteriological investigations of the blood were made In the first a purulent discharge from the umbilicus was noticed a few days after birth Multiple and fairly extensive hæmorrhages occurred ten days afterwards The infant died on the thirteenth day At the necropsy, in addition to the features already noticed, blood stained fluid was found in the pleural cavities, there was double pneumonia and hæmorrhages were also noted in the mucous membrane of the stomach and intestines and into the substance of the kidney Examination of the blood and organs by means of cultivations showed large numbers of streptococci with a few staphylococci In the second case pneumonia developed on the tenth day and death took place two days later At the necropsy hæmorrhages were found in the pericardium, beneath the dura mater, in the pia mater and in the substance of the brain On similar examination of the blood, staphylococci were found in large numbers The hæmorrhages could not be ascribed to injury, the labours were perfectly natural, although in each case premature In the first case the infection most probably took place by the umbilicus

SMALL-POX AT SOUTHAMPTON

SMALL-POX has, we regret to say, been again introduced into Southampton by shipping and, curiously enough, it is by the steamship *Tamar* again that the introduction has been effected The disease appeared on board between Pernambuco and Lisbon, at which place two sailors were put ashore suffering from small pox About a week after arrival at Southampton one of the ship's stewards was notified to be suffering from small pox. Owing to the fact of there being no available hospital accommodation (the house which does duty for an infectious hospital being filled with cases of another disease) he could not be isolated except at home. How this was carried out is shown by the result which followed—viz.,

that some dozen cases which have occurred since are all more or less traceable to the steward of the *Tamar*. Since then isolation in the present hospital has been insisted upon and a temporary iron hospital is being erected on the hospital site. Moreover, revaccination is being extensively practised at the instance of the town council and the guardians. We can only trust that these measures may prove effectual in limiting the progress of the epidemic. But it is to be feared that the unsuitable position of the hospital now in use, as well as that of the temporary adjunct, will but intensify the present danger to Southampton. In the interests of the town the council should lose no time in procuring a more suitable and permanent site.

"APOPLEXY OF THE PANCREAS ATTRIBUTED TO SEA-SICKNESS"

DR. HADE describes a case of so-called apoplexy of the pancreas occurring in a female, in consequence apparently of prolonged and violent sea sickness. The symptoms were analogous to those of peritonitis, there were severe pains on the right side of the abdomen and considerable distension with flatus. The patient died three days after being first seen. The kidneys were found to be granular and there was a large mass of extravasated blood, originating in the pancreatic artery, spreading over the whole of the pancreas and forcing its way to the two kidneys, which were enveloped in blood clot.

PROFESSIONAL TOUTING

THE Pathological Society of Reading in Berkshire is believed to be the oldest society of the kind in the kingdom, having been founded in 1841. The medical men of the borough and counties adjacent who are members of this Society at their meeting on Jan. 4th determined to take some steps to check the growing tendency to lower professional status by the practice of circulating printed statements amongst the public, setting forth the conditions and terms on which they can be attended and supplied with medicines by becoming members of a "medical aid society." As the result of a full discussion the following resolutions were passed: 1. "That in the opinion of this Society the honour and interests of the medical profession are insufficiently safeguarded, and we do request the General Medical Council to use the powers vested in them, or if necessary to acquire larger powers to enable them to deal with conduct (other than criminal) dishonouring to the medical profession." 2. "That this Society regards as unprofessional all toutting advertising or covering or the holding of any appointment where it is shown that such means are employed to increase the sphere of work."

BURIAL AND CREMATION A PROPOSED COMMISSION OF INQUIRY

THE objects aimed at by the deputation of the Church of England Burial Reform Association which recently waited upon the Home Secretary were well worthy of the attention which they received. They included, as our readers will remember, besides the appointment of a Minister of Health—a matter referred to in our leading article on "The Ministry and Public Health" (vide p. 93)—a proposal for the more careful certification of causes of death and another for the institution of an exhaustive inquiry as to the comparative merits of the different methods of burial now recognised amongst us. We observe with much satisfaction that Mr. Asquith appears to be sanguine as to the feasibility of carrying into effect both of these latter propositions. There can be no question as to their importance. It cannot be denied that, notwithstanding the general practice and the recognised utility of death certification, there still remains a considerable annual margin of deficiency represented by cases in

which the dead are allowed to reach their last resting place without any official notice of the means whether natural or other, by which they died. As regards the practice of burial in its relation to cremation and the relative advantage of different modes of interment, there is, in our opinion, hardly any sanitary question which requires more careful discussion or which as yet owes so little to the deliberate declarations of authority. We would most sincerely welcome the appointment of a commission of inquiry which would examine the present state of our knowledge upon this important subject and would publish the result of its investigation in a definite statement of opinion.

THE LANCET RELIEF FUND

THE "Application Form" of THE LANCET Relief Fund will be found in our present issue. It can easily be removed, filled up and forwarded to the Secretary, Mr. Edward Davies, THE LANCET Offices, 423, Strand, London. We would once more ask those of our readers who may have occasion to employ the form or to sign one of the required accompanying certificates to carefully notice the conditions on which applicants become entitled to a participation in the benefits of the Fund.

"FAITH CURES"

THIS subject has been recently discussed in the pages of one of our contemporaries by so able a physician as M. Charcot. His treatment of the subject is very calm and impartial. After showing that in all ages the conditions affecting the successful application of the faith cure have been practically identical, he emphasises the following important points: (1) That a special disposition on the part of the patient is necessary to success—a disposition fostered by the mental exaltation incidental to religious pilgrimages, (2) that the diseases usually benefited have been of a convulsive or paralytic order—that is they belong to the category of functional disorders "which demand for their cure no intervention beyond the power which the mind has over the body", and (3) that the domain of faith healing has thus a limited application. M. Charcot, however, deals with the matter in no dogmatic spirit nor does he restrict within too narrow limits the trophic influence of the nervous system. Mention is made of the remarkable case of a patient in whom a "hysterical oedema" of the breast resulted in extensive and long-continued sloughing and who was at the same time the subject of a profound hysterical paralysis of the left side. The sores, mistaken for cancer, rapidly healed and the paralytic symptoms disappeared.

ASLEEP OR DYING?

OF somewhat more than ordinary interest and importance was one of the cases recently inquired into by a coroner's jury at St. Helens. It was that of a woman who probably while intoxicated, fell downstairs, and striking her head against a wringing machine sustained what finally proved to be fatal concussion of the brain. The most singular circumstance observed in connexion with the occurrence was the fact that the deceased was allowed to lie in a state of stupor for eighteen hours before her relatives considered it needful to send for medical assistance. It was the old story over again—the stupor of cerebral compression was mistaken for drunken sleep. Perhaps in the existing circumstances it was not remarkable that the other occupants of the house—her husband and son both over-tired with a week's labour and half asleep themselves—should at the outset have fallen into this error, notwithstanding the existence of a bleeding scalp wound. Dangerous head injuries as every practitioner can testify, often wear at first and for some time afterwards an appearance of deceptive innocence. Their true character, unless it be carefully looked for, at the time of infliction, is usually

reverted, only when too late for remedy, by the signs of serious brain mischief and this fact is of even more professional than general importance. It would not be surprising if death were in this instance accounted for by an excusable ignorance of the true significance of the head injuries. As it happened, however, the symptoms of grave illness were present and the absence of any real interest on the part of relatives was conspicuous. A verdict of accidental death was perhaps the only one possible, but the coroner did well to emphasise his opinion of the flagrant neglect which delayed till so late the arrival of skilled assistance.

SMALL-POX IN SCOTLAND

SMALL-POX has shown renewed activity during the past week in Glasgow. A new centre of the disease was discovered on the south side of the Clyde and a number of the fresh cases are related to it. At Ardlin on Loch Lomond three or four cases have developed among persons who had been placed under observation owing to their having been exposed to infection from the case which we reported last week. The navvies' hut in which these cases occurred has been turned into a temporary hospital and an adjoining hut has been placed by the contractors at the disposal of the sanitary authority as a reception house. This week a case has occurred in a navvies' hut on the Helensburgh section of the West Highland Railway. In this instance the infection appears to have been brought by a tramp from Glasgow. Revaccination and isolation are being carried out in connexion with this case. The following table shows the movements of the death rate of Old Glasgow since the commencement of registration in 1855—

Mean death rate 6 years	1855-60	29.9
" " 10 "	1861-70	30.4
" " 10 "	1871-80	23.0
" " 10 "	1881-90	24.5
Death rate for	1891	26.3
" " "	1892	23.0

The death rate of Old Glasgow has only on two occasions—viz, in 1888 and 1891—been less than in 1892. The following is a summary of the year's work in the vaccination department—

Primary vaccination at station	1892	1891
Secondary vaccination at station	809	350
(At home)	195	45
	1010	145

The Registrar General estimates the population of the city for 1893 at 677,877, in place of 669,059—an increase of 8818. For the fortnight ending Saturday at midday, 18 cases of small pox were reported. Two of these were reported in the first week of the fortnight, and 16 in the second, and these within the last few days of the second week. Reckoning from Wednesday, the 4th inst, till Wednesday, the 11th, 25 cases were reported.

THE "MANIA PELLAGROSA"

PELLAGRA in Italy is on the increase. True, it is not in itself a deadly disease. In 1888 for instance, the general mortality reached the figure of 829,431, while the victims who succumbed to pellagra were 3483. But it is a disease very disastrous in its sequelæ one of which is a distinct mental neurosis manifesting itself in what has been classified as "mania pellagrosa." In Lombardy, the headquarters of pellagra, the *manicomii* (lunatic asylums), according to Professor Sormani of Pavia, show a large proportion of the "pellagrose insane," those of Milan heading the list. In 1885 the Milanese *manicomii* admitted a total of 122 pellagrosi with 44 deaths, in 1886 a total of 147 with 45 deaths, and in 1887 a total of 105 with 46 deaths. Professor Sormani demonstrates that while pellagra in general is on the increase, the mortality from it becomes more than proportionately heavy, and that the most numerous victims who succumb to it fall under that peculiar (and also increasing) form of it—

"mania pellagrosa." To combat this deplorable phenomenon prevention rather than cure is the course indicated. But, meanwhile, in the Milanese provinces there has been erected an "Asilo de Pellagrosi," where the treatment, mainly dietetic, is practised, from which the Legislature may be guided to the best means of averting the malady at its origin. That treatment consists in the substitution of a mixed farinaceous and meat diet for that exclusively meted out to the labourer—namely, the polenta (porridge) of meal made from unsound maize, which is his hereditary fare. Good broth, with milk, and a graduated allowance of wine, replacing the polenta above described, suffices to put the young pellagrose patient on the true alimentary track, while in more confirmed cases—those in which neurosis is already apparent—the same diet, coupled with a judicious use of alteratives and tonics, seldom fails to bring about physical and mental convalescence. At this stage the resumption of out-door or fieldwork comes in to complete the reclamation of the "pellagroso," and he leaves the "Asilo" a fitter man, capable of better work and thus enabled to give himself the more generous diet he has found to be necessary for body and mind. The "Asilo" which has thus afforded an object lesson to the individual and to the State in dealing with pellagra stands in the commune of Inzago and its success is stimulating the charitable throughout the Alta Italia to erect others with a similar object—chiefly in the Lombard and Venetian territories. Practical legislation on the part of the Government has yet to intervene for the improvement of the labourer's lot in that region—the more equitable incidence of taxation and the provision of public employment where private enterprise is insufficient. Works on an imperial scale, such as the replanting of the recklessly denuded hill sides, the regulation of the affluents that feed the great rivers and the embanking of these latter—works imperatively called for to prevent the disastrous floods that annually devastate the Venetian province particularly—might profitably engage the services of those for whom there is barely employment enough in the fields. Professor Sormani, meanwhile, can claim this result—of having demonstrated that prevention, not cure, is the proper way of dealing with this Italian scourge and that the appointment of commission after commission to "investigate" the phenomena is merely a political makeshift, to relieve the State of its obvious duty.

FOREIGN UNIVERSITY INTELLIGENCE

Bologna—Dr P. Pellacani, Extraordinary Professor of Forensic Medicine, has been raised to the rank of Ordinary Professor.

Brussels—An institute of Bacteriology is shortly to be erected by private munificence near to the Physiological Institute.

Leipsic—Dr Rudolf Armin Fick of Würzburg, a son of the great physiologist, has been appointed to an Extraordinary Professorship.

Messina—Dr Seimoni has been raised to the rank of Ordinary Professor of Ophthalmology.

DR. GUIDO BACCELLI delivered in Rome, on the 5th inst., the first of a series of lectures instituted by the Association for the Education and Instruction of Women. The Queen of Italy was present and the brilliant audience reflected the *élite* of Roman society. The lecturer chose as his theme the Vestal Virgins, and after a most interesting account of the excavation of the Atrium Vestæ effected, when he was Minister of Public Instruction, by the great archaeologist, Signor Lanciani, he dwelt on the characteristics of the Vestals as illustrating the sovereign female virtue of purity, constancy, dignity and faith. The lecture, which was highly successful, will be made *publici juris*.

In reference to the appointment of a Professor of Anatomy in the University College, Cardiff, the *South Wales Daily News* says "In connexion with the new school of medicine to be founded next October at Cardiff, a rumour has unfortunately become prevalent that it is useless for outside men, however eminent, to send in an application for the professorship of anatomy, as it has been practically decided to give the appointment to a Welshman. On inquiring into the matter we learn that there is not only no foundation for the rumour, but that the College Council cannot possibly account for such a rumour being prevalent. Throughout the whole career of the College the Council has steadfastly kept one aim in view—viz., to appoint the candidate possessing the highest qualifications to the vacant post, and never on any occasion has this principle been set aside. This is one of the main reasons why the University College, Cardiff, has been so successful, and the same rule will unquestionably decide all the appointments for the new school of medicine."

THE programme for the series of lectures to be delivered at the Royal Institution in the spring of this year appears to be of more than usual interest. On the list will be found a series of ten lectures to be given by Professor Victor Horsley in January, February and March, on the "Structure and Functions of the Nervous System—The Brain," commencing on the 17th of the first-named month and terminating on March 21st. Also, on Feb 10th, Professor Charles Stewart will discourse on "Some Associated Organisms," a subject which the lecturer may be trusted to deal with to the entire satisfaction of his audience.

THE recently appointed coroner for West Middlesex, Dr W B Gordon Hogg has chosen as his deputy Dr William Wynn Westcott, who has acted for ten years past as Deputy Coroner for Central London. The nomination has been officially approved by the Chairman of the County Council, as required by the Coroners' Deputies Act, 1892.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on the 10th inst., T Russell Pickthorn, Esq., Inspector General, in the chair the sum of £43 was distributed amongst the several applicants.

BARON HIESCH has forwarded to the committee of the North Eastern Hospital for Children a donation of £700, and to the Royal Hospital for Children and Women, Waterloo-bridge-road, a second donation of £700.

CHOLERA.

CURRENT NOTES COMMENTS AND CRITICISM

THERE is not much to record in regard to the progress of cholera during the past week, but what there is is significant in two directions—viz., that it is indicative of the widespread distribution of the epidemic and of the localised persistence of the disease at Hamburg as shown by the appearance of an occasional case of cholera there. We learn from Constantinople in the *Lerant Herald* that between Dec. 25th and 26th last 2 cases of cholera and 6 deaths had occurred at Trebizond. A Commission met on Dec. 27th at the Ministry of the Interior under the presidency of His Excellency Refik Bey of the Home Office to discuss the sanitary measures which it is proposed to carry out in Trebizond with the view of arresting the progress of the disease in that district. In the village of Ketch 6 cases and 2 deaths were registered between Dec. 20th and 24th and one death is reported in the village of Badosh, in the province of Van. A few cases have continued to appear in Galicia, for example, since the 22nd ult. there were 12 cases and 5 deaths from cholera at Zalosze and three other districts in Galicia.

As regards Hamburg, after four days' immunity, a fresh case was reported on the 9th inst. in the person of a labourer living in the Steinstrasse and there was one death from cholera at Altona. On the 10th inst. it was reported that two of three sailors removed to hospital from a Spanish steamer, *Murciano*, had been found to be suffering from cholera and had died. Another case in the persons of a man recently released from prison had also occurred. It appears that two Spanish steamers—the *Murciano* and *Zaria*—which had entered the port of Hamburg were found to be in an almost indescribably filthy condition, especially the former which arrived from New Orleans on the 5th inst., but the affected men seem to have been attacked before the arrival of the vessel at Hamburg.

According to the *Times'* correspondent the probable source of infection in the cases from the *Murciano* was from the use of Elbe water. Be this as it may, the river has not stood for many years so low as it does at the present time; and it is pointed out that on the occasion of the cholera outbreak at Hamburg last summer the river was exceptionally low.

A fatal case of cholera occurred at Amsterdam on the 11th inst. and a fresh case of Asiatic cholera is also reported from the Hague.

The *American Journal of the Medical Sciences* for the present month contains three papers in connexion with the history of cholera in New York in 1892 and the results of the bacteriological examinations that had been carried out. The first vessel infected with cholera to arrive at New York was the *Moravia*, which left Hamburg on the 6th and arrived at New York on Aug 31st, 1892. She reported 22 deaths during the voyage from gastro-intestinal disease. Three days after the arrival of the *Moravia* the *Normanna* and *Rugia* reached New York. The first person affected with cholera at New York was taken ill on Sept. 5th, five days after the disease had appeared in the harbour, and died on Sept 7th. During the four weeks following 6 other cases occurred in that city and 1 case in New Brunswick, N J. Dr Hermann M. Biggs in his article on the late outbreak of epidemic cholera in New York, says that his experience in 1892 and previously at the quarantine station in 1887 convinced him of the great practical value of bacteriological examinations in the diagnosis of Asiatic cholera, and of their importance in assisting the work of the Health Department. Reviewing the history of the outbreak in New York, he summarises his conclusions as follows:

"In no single instance, after the most careful and conscientious inquiry and investigation, was it possible to find any satisfactory way of accounting for the infection. The cases occurred in widely separated parts of the city and in no instance was there the slightest suspicion of association. After the cases were brought to the attention of the Health Department, in no instance did a secondary case occur. There was a striking association in the occupation of the persons affected with the food trades and especially animal foods. Although some 26 suspicious cases were examined, in every one in which the cholera spirillum was found, 8 in number death occurred, while in only one of the other cases in which the cholera spirillum was not found did death follow. In two instances however, where recovery took place—that is the fifth and sixth cases—although biological examinations were not made, the associations with cases which were proven to be cholera Asiatica justified the assumption that these were of the same nature." The *Indian Medical Gazette* for last month has, on the other hand a very important article bearing upon the pathology and bacteriology of cholera, based upon the reports of Surgeon-Lieut Colonel D D Cunningham, F.R.S. and other officials in connection with the recent tragical outbreak on board the *Crofton Hall*. We may succinctly recapitulate the facts regarding this occurrence as set forth by our Indian contemporary. The ship *Crofton Hall* was lying in the Hooghly on Jan 20th, 1892, at which date her second officer prepared some fresh brine with water taken from the river for the preservation of some beef received on board at New York. The vessel remained in the river until June 2nd following during which time the beef remained for some of the hottest time of the year in what is called a 'harness cask,' the crew being rationed from the shore. The salted beef was issued on June 4th, 5th, 7th, 9th and 12th respectively, after the vessel had left the port of Calcutta, and the issues were followed on each of the following days by symptoms resembling cholera among those who partook of the meat. Twenty three out of

a crew of twenty nine were attacked, and 6 cases died among 14 of those seized during the first four days of the outbreak. It is important to note that no sickness occurred on those dates when the salt beef in question was not issued. The ship returned to Calcutta owing to this sickness among her crew, and ten of the remaining sick were at once sent to the General Hospital for treatment. The medical officers of that institution were unanimously of opinion, however, that these ten men were not suffering from cholera. The absence of depression of temperature and suppression of urine, the presence of pustular eruptions or abscesses in a large proportion of the cases and other phenomena, together with the fact that all ultimately recovered, whereas the death rate of cholera among Europeans ranges from 50 to 75 per cent. in that climate, left no doubt on the minds of the medical staff that the disease was not true cholera. An exhaustive investigation was also undertaken by the health officers of the port and town of Calcutta which proved in the clearest manner and beyond any doubt that the outbreak was due to the issue of the meat from the harness cask. Unfortunately the remains of the suspected meat were thrown overboard, but specimens of the brine in which the meat had been soaked were taken away and carefully examined by different officials and by Dr. D. D. Cunningham, who also examined bacteriologically the excreta from the patients admitted into the Calcutta Hospital and the micro-organisms found in the stools. The papers connected with this inquiry, and the Government resolution thereon, were published in the *Calcutta Gazette* of Sept. 30th, 1892, and, according to our contemporary, form a very clear and complete history of the occurrence. The cause of the disease was naturally attributed to poisoning from some ptomaine developed in the partially decomposed salt meat, of which the men had partaken.

The brine had a peculiar fetid odour and acid reaction and was crowded with bacilli of different kinds but, as might have been expected, there were no comma bacilli present. Dr. Cunningham's examination of the stools of the patients showed, however, that in one of the cases the flocculi were occupied by very abundant and almost pure growths of well formed comma bacilli, and both plate and tube cultivation, especially the latter, gave comma bacilli in abundance. When cultivated in ordinary gelatine and in agar agar these comma bacilli liquefied the gelatine and behaved exactly in the same manner as organisms of the same shape are found to do when associated with true cholera, producing also after forty-eight hours cholera purple with nitric and sulphuric acids. It may be mentioned, moreover, that cats fed with the cultivations obtained by Drs. Ranking and Simpson from the micro-organisms of the brine gave rise to diarrhoea and in one case to vomiting in those animals. The *Indian Medical Gazette* summarises the salient points as follows—An epidemic clearly produced by the consumption of partially decomposed salt meat, giving rise to symptoms clinically distinguishable from those of true cholera, and micro-organisms, consisting chiefly of straight bacilli and yet comma bacilli, differing in no essential from those discovered in true cholera, were found in abundance in the stools of one of the men admitted into hospital. The importance of the observation consists of course in the fact that it is opposed to the current belief that true cholera can be absolutely diagnosed by the presence of these bodies in the stools. Our contemporary rightly regards these observations as of great interest at the present time and adds that it is not at all uncommon to find an abundance of morphologically comma bacilli in the intestinal discharges in cases of diarrhoea, a very striking example of which, it states, presented itself last year in a case of artificially induced diarrhoea in the person of a prisoner in the presidency gaol. What renders the present instance remarkable is that the comma bacilli are cultivatable under the conditions favourable to the growth of those associated with true cholera and present features showing that they belong to the same group of organisms as the latter. After a logical analysis of the views specially advocated by Professor Friedrich of Berlin and others and of the difficulties involved in the belief that all the very distinct forms of comma bacilli found by Dr. Cunningham and others are to be regarded as "atypic varieties" of one and the same organism, our contemporary leads up to the conclusion that the association of comma bacilli with cholera can no longer be regarded as peculiar and specific. If we remember aught, Professor Koch originally described his specific organism, when discovered in cholera cases in Egypt, as a straight bacillus resembling one which had been found in

glanders, and it was not until after the German Commission had proceeded to India that, in 1883 and the early part of 1884 it was described as curved, or comma shaped, and not straight.

HEALTH OF THE ITALIAN ARMY

THE War Office of Italy has just issued its medico-statistical report on the sanitary condition of the Italian Army during 1891—the last statistical year. It is compiled from the returns of the "Ispettorato di Sanità Militare" and its editor and commentator is the medical inspector, Colonel Santanera, M.D.

A sensible increase in maladies and in mortality during 1891 is the unsatisfactory conclusion of the report of that year as compared with those of its predecessors.

The causes of this increase are sought in the fact that in 1891 there were called under arms two classes of conscripts—"it being known that it is precisely in the early months of service that levies most easily take ill and that their maladies most often run a fatal course."

The insanitary results of 1891 are the gravest of those within the last quadrennium. In 1887 there were per 1000 men of the mean force 760 admissions into hospital and 8.7 deaths, in 1888, under the same heads, the numbers were respectively 732 and 8.7, in 1889 they were 749 and 8.0, in 1890, 796 and 7.5, and in 1891 as many as 811 and 9.0. The individuals admitted into the infirmaries of the several army corps in 1891 were 89,977. Of these, 14,671 passed from infirmary to hospital in continuation of their cure. In the military hospitals and in the garrison and special infirmaries (*infermerie presidiarie e speciali*) there were admitted 88,085 patients—that is, 87,116 directly and 969 from other hospitals.

The mortality among officers was always, and in high proportions greater than that among common soldiers, while it was invariably lower among individuals not belonging to the combatant arm. On this subject Dr. Santanera says—

"The deaths of officers admitted into hospital are uniformly in excess of those of the other categories of admissions, for the reason that in general the officer enters hospital only for grave illness. The mortality amongst non-combatants (sentries on guard at the Ministry of Finance or at Government banks, at municipal halls and at prisons, and exceptionally the military marine) is always lower than amongst combatant troops, chiefly because their off-duty hours are much more numerous than in the army, while their age is generally superior to that of the regulars, among whom ailments and mortality are most frequent amongst the youngest."

The regiments and the corps that in 1891 yielded the largest contingent of patients were the grenadiers, next came the field artillery, next the infantry of the line, then the cavalry, then the engineers. The smallest number on the sick list was found among the Royal carabinieri.

In 1891, moreover, as in the previous statistical years, the health of the army was at its worst in the winter months. Ailments reached their highest figure in February, deaths were most frequent in March.

The maximum of unhealthiness (1046 per 1000) was attained in the Perugia division, the minimum (621 per 1000) in that of Turin. The maximum of mortality (14.3 per 1000) was found in the division of Bologna, the minimum (6.3 per 1000) in that of Alessandria. Finally, the maximum of those put on sick leave (27.7 per 1000) is shown by the Bologna division and the minimum (5.7 per 1000) by that of Ravenna.

Within the last quinquennium the mean of mortality was always exceeded by the divisions of Padua, of Rome, of Perugia, of Naples and of Bari. The mean of those put on sick leave was exceeded as in the four years preceding, by the divisions of Brescia, Bologna, Florence and Perugia. The mortality, on the other hand, which up to 1890 was always above the average in the divisions of Genoa and Naples, was in 1891 somewhat, though not much, lower in these latter.

The maladies which numbered more than 1000 patients each were the following: the highest being given first—Venereal diseases, 15,809, acute bronchitis, 10,056, rheumatic fever, 5365, malaria, 4232, acute gastric catarrh,

165, pleuritis, 2947, simple gunsy, 2745, and rheumatoid arthritis, 2517

The aggregate number of deaths among the troops in 1891 as 1978, or 9 per 1000 of the mean force, the officers of the landing army who died were 124. Deaths by infective disease underwent some increase, on the other hand there was diminution in tuberculous cases and suicides. The proportion of these was 0.33 per 1000.

The garrisons on the Red Sea littoral gave an average of 1.75 sick per 1000 of the force, which, excluding the indigenous soldiery had a mean of 2603 men with a maximum of 648 in March and 1796 in number during October.

To the admissions into infirmaries and hospitals during 1891, adding 157 remaining over from December, 1890 there were, for the garrisons of the Red Sea littoral, a total of 3215 under treatment, of whom 1439 were hospital and 1776 infirm patients.

The losses by death during 1891 were, on that littoral, 36 in all—that is, one officer and 35 men.

The average of the mortality of the troops was hence in the aggregate 19.4 per 1000 of the force, while with restricted reference to the sick under treatment in hospital and infirmaries the mortality itself is reduced to 9.7 per 1000—that is, 5.5 in hospital and 9.9 in infirmaries.

Comparing the figures above given with the corresponding ones of the year before, it is seen that in 1891 the sanitary condition of the troops on the Red Sea littoral was somewhat improved, if not on the side of disease, at least on that of death.

To aggravate the death rate in 1891 the cholera made its special contribution. From this epidemic, though much restricted and of very brief duration, there died six. Deducting these, the mortality of the troops remains 11.1 per 1000 of the force.

The greatest amount of disease was in November, a fact attributable to the exceptional development of malaria in some garrisons and of rheumatic fever in others, due to the inclemency of the season.

Dr Santanera's report contains other matter of much sanitary interest, civil as well as military. But the statistics above given exhaust the details bearing particularly on the health of the Italian army.

A CENTRAL OPHTHALMIC SCHOOL FOR LONDON

By SYDNEY STEPHENSON, M.B., F.R.C.S. EDIN.,
SURGEON TO THE HANWELL OPHTHALMIC SCHOOL.

THE proposal to isolate cases of ophthalmia, in an institution where treatment might be carried out together with schooling, was advanced twenty-four years ago by the late Mr. Critchett. It has been urged since then by Dr. Bridges and by Mr. Nettleship and also by Mr. H. J. Searle, chairman of the Central London School District. A practical attempt at dealing with epidemic ophthalmia was made in 1886 at the Norwood Schools, which belong to the parish of Lambeth. The guardians engaged my services and placed at my disposal a modern building and a good staff of nurses. After two years I was able to say that the attendance of an ophthalmologist was no longer required. As regards other parochial schools it is not going too far to say that ophthalmia has more than once given grave cause for anxiety in every one of them. This has been specially the case at the Strand and the Forest Gate Schools, where steps have been taken involving the expenditure of considerable sums of money. Furthermore, it is practically certain that under present conditions they will never be safe from future outbreaks. Indeed, the necessity for dealing with the disease in a radical manner must by this time be obvious to most people, and it appears to me that the present is a particularly opportune moment for urging the claims of a central ophthalmic school. An ophthalmic school was erected two years and a half ago at Hanwell to receive 400 children, but for some time past it has contained less than 100 patients. This waste of accommodation led me in July last to suggest in my report to the managers that they should throw open their institution to other metropolitan unions. Shortly afterwards the Local Government Board made a similar suggestion, which the Hanwell managers, however, profess themselves unable to adopt. At the same time they are willing to dispose of the buildings to any properly consti-

tuted authority, but so far, no answer has been received from the Local Government Board to the latter proposition.¹ From a report published by Dr. Bridges in 1890 one learns the significant fact that during the previous seven years not a single parochial school remained wholly free from ophthalmia. Tables appended to that report show the number of children invalided by the disease on fourteen specified dates between the years 1883 and 1889 inclusive, and a calculation of some interest may be readily made from the data thus supplied. To obtain the following figures I have taken the average number of children and the average number of ophthalmic cases for the seven years covered by the report, and from these have calculated the average percentage of ophthalmia for each school. The results arrived at are suggestive. Hanwell heads the list with an average of 16 per cent., Norwood comes next with 9 per cent., Edmonton and Sutton, 5 per cent., Banstead road, Leavesden, and Brentwood, 3 per cent., Anerley and Hurold Court, 2 per cent., Ashford, Forest Gate, Leytonstone, Southall and Mile-end, 1 per cent., and lastly, remaining institutions showing less than 1 per cent. of ophthalmia. It is interesting to observe that on the last date given by Dr. Bridges (July 6th, 1889) no less than 598 cases of ophthalmia were under treatment in the various schools. During the last two years the City of London and the parish of St. Saviour's have sent to the Hanwell Ophthalmic School 128 affected children, only 28 of whom had previously been inmates of a pauper school. Again, a considerable number of children suffering from ophthalmia are at this moment detained in the Lambeth workhouse and infirmaries because the medical officer at Norwood very properly refuses to admit such cases into the school. These facts show that among the fresh admissions to the London workhouses are a number of children who have already contracted the disease outside. "Granular lids," as most people know, drags its tedious course over a number of years, so that cases must accumulate in the infirmaries. On the other hand, to send affected children to schools that have not proper accommodation would be to court disastrous outbreaks of ophthalmia. A central ophthalmic school would receive not only existing cases of ophthalmia from the various schools, but also all children thus affected on admission to the workhouses. The metropolis has upwards of 11,000 pauper children distributed amongst eighteen schools belonging to different unions. Each school has therefore to deal with its ophthalmic cases as best it can. Complete isolation is now admitted to be essential for the prevention of ophthalmia, but it is clear that in most schools such isolation is at present impossible. When an outbreak occurs the infirmaries become quickly filled and the children overflow into the school itself. It is possible that some at least of the widespread outbreaks recently witnessed would never have taken place had a system of rigid isolation been consistently in force. Should a school determine to grapple efficiently with ophthalmia the attendant expenses will necessarily be heavy. At Hanwell, for instance, upwards of £30,000 has been spent on the erection of a suitable isolation school, while at least £4000 have been expended on salaries already. The direct and indirect expenses of the recent outbreaks at Norwood, Forest Gate and Edmonton must have been proportionately heavy. The certainty of incurring pecuniary burdens of this sort is scarcely calculated to encourage action on the part of boards of guardians, yet it is obviously to the interest of the community that such steps should be taken. Individual boards, however, would feel no hesitation in sending affected children to a central institution to which each union contributed. Regarded from an economic standpoint a central school would be more efficient and less costly than would be possible in any scheme initiated by a single union.

Turning now to the educational aspect of the proposed scheme it can hardly be questioned that teaching would be better carried out in a well equipped central school than could possibly be the case in scattered buildings set apart haphazard for diseased children. At Hanwell the majority of the patients have been found able to accomplish twenty-three hours' schooling a week, and at the examination recently held by Her Majesty's inspector they obtained 90 per cent. of passes. If local treatment be persevered with I find that ophthalmic patients are capable of undergoing almost as

¹ Since the above was written three metropolitan boards of guardians have formally approved the scheme of central isolation for ophthalmic children. These boards are Lambeth, Camberwell and Bethnal Green. The last has attempted, indeed, to open up direct negotiations with the Hanwell managers.

much schooling as ordinary children, and in organising any scheme of tuition that fact should be kept in view.

The question remains as to what body is to assume the reins of government. It is to be hoped that the Metropolitan Asylums Board, which already controls numerous medical institutions, will see its way to take this added responsibility, otherwise it would be feasible to create an entirely new authority consisting of representatives from all the unions interested. In whatever hands the management may ultimately be vested, it is, I think, of great importance that the whole of the metropolitan schools should be in touch with the proposed institution. To secure that end it would be well to maintain the school, not by contributions from individual unions, but directly from the Metropolitan Common Poor Fund, thereby spreading the charge over the whole London district.

The adoption of a scheme for the collective treatment of ophthalmia, such as I have outlined in the above remarks, is, I would submit, a matter of pressing importance. Such a scheme, placed on a sufficiently broad basis, appears to offer the only satisfactory plan of coping with a disease that has been a scourge in the pauper schools of London from time immemorial. A suitable building is ready and waiting at Hanwell. Should not advantage be taken of so hopeful an opportunity? It would be the conversion of a scientist's vision into a substantial, a praiseworthy and a salutary reality.

Welbeck-street, W

THE CONFERENCE ON CHOLERA IN ST PETERSBURG

(FROM OUR SPECIAL CORRESPONDENT)

(Continued from p. 52)

DR. GREBENTCHIKOFF, continuing his statistical account of the epidemic and of the mode of its dissemination, stated that the first case of cholera in Russia occurred in Kaachka, a station on the Transcasian Railway, on May 19th (31st). The channel by which the infection crossed the frontier is unknown. Many other parts of the Transcasian and Samarcan provinces were affected in May and June, and from June 6th (18th) suspicious cases began to be admitted into the Baku hospitals. How the disease reached Baku is unknown, but there is evidence that the first patient there was a foreign labourer, who had come from Persia through the Transcasian province and who stayed at a certain house in Baku which became one of the chief centres of infection in that town, furnishing no less than forty patients in the first week of the epidemic. The disease raged violently in Baku, and the panic-stricken inhabitants fled in all directions, carrying the infection with them. In the first half of June cholera had affected most of the towns lying on the Caspian Sea and had penetrated into the Caucasus. Thence it travelled to Europe by two great routes—on the one hand by the Volga and on the other by railway to the basin of the Don, the first of these being by far the quickest. The speaker proceeded to trace the course of the epidemic by each of these routes, enumerating the "governments" or provinces affected during each succeeding month. He exhibited the following table, showing the area and population of the districts in which the disease was present during each of the months from May to November. The whole of these immense areas was of course not actually affected by cholera. Many large districts remained free from the disease, but every "government" has been included from which a return has been received, although only one "uyezd" (district) or even only one village in the "government" may have suffered from the disease. With this limitation the disease was present

In May	over	484 000 square versts with	700 000 inhabitants.
In June	2 763,000	"	15 286 000
In July	7 271 000	"	63 408 000
In August	7 645 000	"	77,595 000
In September	7 808 000	"	87,848 000
In October	6 965 000	"	87 725 000
In November	1,682 000	"	69,767,000

The disease has spread mainly along the course of the rivers, it affected the whole systems of the Volga, the Don, the Dnieper, the Ural and the Obi, every part of the Central Asiatic provinces, the systems of the Vistula and Western Dvina and finally the whole of the St Petersburg district and two "uyezds" of the Olonetz governments.

From a table of the numbers of cases and deaths reported from every government throughout the Empire to the beginning of December it appeared that the Caucasus suffered most severely from the epidemic, the second in order of severity being the Central Asiatic provinces, the third Siberia, particularly the government of Tobolsk, and finally the country of the Don Cossacks and the following European governments Astrakhan, Saratof, Samara, Simbirsk, Voronez, Orenburg and Tumbof. Charts were shown indicating by curves the course of the epidemic week by week in every government, and from these it appeared that the cholera rapidly (in the course of two or three weeks) attained its greatest intensity, that it remained at this height for one or two weeks, and then in a few districts gradually subsided, but more often there was a remission lasting one or two weeks, then the curve again rose, the second rise being followed by a gradual fall. In certain towns even a daily chart showed a similar double rise and remission. The means by which cholera was introduced into a given locality have remained in the immense majority of cases unknown. In twenty-eight governments, however, information had been furnished to the Medical Department on this point and the speaker proceeded to repeat in detail each of these cases. The general conclusion to be drawn was that pollution of the drinking water was in almost every case the channel by which the disease was spread.

Professor Janson, the Professor of Statistics in the St. Petersburg Academy and author of several important works on economical questions, read a short but interesting paper on the Value of Statistics. He pointed out the importance of recognising the first case of cholera or any other epidemic disease. The only certain means of doing this was by a thorough and constant system of notification and registration of all diseases, more particularly of infectious diseases. He recommended the adoption of registration of deaths such as is in use in all Western European countries. He also dwelt on the necessity of recording all the circumstances surrounding every case of an epidemic illness, as only in this way can general conclusions on any particular point be arrived at.

A paper was read by Dr. Tolstoi on Precautionary Measures directed against the Dissemination of Cholera. In discussing the question of quarantine he pointed out certain anomalies in the quarantine laws existing in ports on the Black Sea. The efficiency of cordons, the medical inspection of passengers, the disinfection of luggage, the measures taken along the rivers, particularly the Volga, were all briefly reviewed. The following questions were submitted to the conference for discussion in committee—(1) Quarantine regulations, cordons and military isolation of places, (2) "observation points," (3) general inspection of passengers, and the following additional points—(a) the means of determining the first case of cholera, (b) the means of localising the infection.

An important communication was read by Dr. Rozanof on General Precautionary Measures before the appearance of Cholera. He discussed the efficiency of the special Sanitary Commissions and their relation to the sanitary authorities already in existence. These commissions, it should be explained, were formed early in June, in accordance with a Government order, in every town forming the centre of a "government" or *uyezd* throughout the country, with the object of improving the sanitary condition of the town and district before the approach of the epidemic. On this subject Dr. Rozanof put the following questions to the conference: 1. To what extent are special sanitary commissions necessary in the struggle with the epidemic in view of the other sanitary authorities already existing? 2. How should such commissions be constituted? 3. What should be their relation to the Government and local authorities? 4. What should be the limit of their powers and what is to be the source of their revenue? 5. What should be the relation between the Sanitary Commissions and the Medico-Statistical Bureaux? 6. What should be the organisation and the duties of subcommissions? (Last summer subcommissions, consisting of sanitary and police inspectors, were formed in each quarter of the larger Russian towns to inspect and improve the sanitary condition of every building in that particular part of the town.) 7. What should be the number and constitution of the bodies of sanitary overseers, inspectors &c., and their relation to the police? Passing on to discuss the many questions relating to the sanitation of inhabited localities Dr. Rozanof pointed out that wherever the sanitary condition of a town or district had been satisfactory the cholera epidemic had either passed it by altogether or claimed but few victims. He deplored the

act that such localities were but few in number and gave several instances of towns in an extremely insanitary condition and quite unprepared to meet an epidemic of cholera as in the other papers the points discussed were put in the form of questions and submitted to the committees as follows 1 Measures of sanitation in inhabited localities 2 The results of sanitary inspections carried out last summer 3 Data for judging of the possibility of cleansing the soil and removing of refuse in towns and villages 4 The means of providing a pure water supply 5 The means of inspecting crowded institutions, such as night refuges, lodging houses, factories &c These questions have been discussed in committee under the presidency of Professor Kapustin and certain conclusions have been arrived at. The committee declare that special sanitary commissions are necessary and very useful institutions, especially in places where there is no medico-sanitary organisation under the zemstvo Where there is such an organisation they are most useful if they act in conjunction with the authorities already existing Their success has been so great that they will probably remain in constant existence, though only formed to meet a special danger The sanitary councils or commissions existing in the Moscow, Saratof and some other governments might be taken as types of institutions which, with certain alterations, could be converted into special sanitary commissions. With regard to their relation to Government and other local authorities, it has been decided that in most cases this should be determined in the constitution of the commission. In order to ensure united action the commissions should have the rights of committees of public health. Finally, as to the limits of their powers the committee consider that this is already provided for in certain articles in the orders of the Medical Council The question as to the necessity for Government commissions called forth a lively discussion and was ultimately decided in the affirmative.

Demonstrations have been given daily in bacterioscopy in the laboratories of the Imperial Academy of Medicine, in the clinical institute named after the Grand Duchess Helena Pavlovna and in the Alexander Hospital in Memory of the Emancipation of the Serfs Demonstrations in disinfection have also been given to members of the Conference in the Oldenberg Institute of Experimental Medicine and in the Alexander Hospital in Memory of Botkin

A report of the proceedings of the Conference will, it is hoped, be published shortly

THE LONDON POST-GRADUATE COURSE

THE spring term, 1893, will commence on Monday, Jan 16th, and will consist of twelve courses of lectures and demonstrations at the following hospitals and institutions viz. the Hospital for Consumption and Diseases of the Chest, Brompton, the National Hospital for the Paralysed and the Epileptic, Queen square, the Hospital for Sick Children, Great Ormond street, the Royal London Ophthalmic Hospital, Moorfields the Hospital for Diseases of the Skin, Blackfriars Bethlem Royal Hospital for Lunatics the London Throat Hospital, the Bacteriological Department, King's College, the Parkes Museum Courses of Lectures and Demonstrations on Morbid Anatomy and Gynecology and a course of Clinical Lectures on Medicine and Surgery at the Central London Sick Asylum, Cleveland street, W The steady growth of the undertaking is well shown by comparing the five courses of the first term with the twelve courses of the tenth, giving 121 entries in 1890, 172 in 1891 and 223 in 1892 The men who enter continue to come chiefly from the British Isles and our own foreign possessions whilst a considerable sprinkling is drawn from the United States of America. Most of the men possess good degrees and high qualifications, and several lecturers from our Colonies have come to study the methods of teaching employed in the metropolis The opening of the Poor Law Infirmary has enabled the committee to invite the cooperation of several distinguished emeritus professors, and their vast experience has thus been made available for clinical teaching whilst a mass of material hitherto unused has been placed at their disposal The medical schools have found that this undertaking in no way clashes with their work, and in fact, serves to supplement it All the varied wants of practitioners, whether they have come from distant parts of the world or

are living in our midst, have as far as possible been met They have entered for a whole term, half a term (one month) or for one week, at proportionate fees, or they have attended all the lectures at one hospital for a term or for half a term, as best suited their wants and wishes A full prospectus can be obtained from Dr Fletcher Little, 60, Welbeck street, W

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH

Kennington Parish—The death rate for this parish during 1891 was 18.4 per 1000, or 1.8 above the decennial average and 3.0 below that for the metropolis as a whole The zymotic rate was 1.6 per 1000 Dealing with this latter group, Dr Dudfield refers to measles and points out that it yet remains to be proved whether great advantage would accrue from its inclusion amongst the notifiable diseases This is a point as to which opinion varies a good deal, but as to which it is to be hoped we may soon have such information as has accumulated in different parts of the country Of 323 cases of scarlet fever that were recorded 206 were removed to hospital. The work of the sanitary inspectors is recorded, as is also the action taken under a number of different headings, such as offensive trades, refuse removal, slaughter houses, dairies &c, but a large part of the volume is taken up with general questions of legislation, the work of the Metropolitan Asylums Board, metropolitan sewage purification &c. In fact, the volume might not only properly bear, but well merit, a title indicating a work of much wider scope

Birkenhead Urban District—This report constitutes the 1st of an excellent series of annual reports by Mr Francis Vacher, who has since resigned his post as medical officer of health. The death rate for 1891 was 20.9 per 1000 the zymotic rate being 2.63, and amongst the latter group of diseases there figured 38 cases of typhus fever a disease the prevalence of which should make Birkenhead determine that it will not rest until it has abolished it Notification revealed 1007 cases of infectious disease, but some cases, including mild cases of typhus fever, must have remained unnotified In another respect the borough needs to mend its ways, for it still retains old fashioned midden privies and refuse nuisances are by no means exceptional Only 47 cases of infectious disease were removed to the isolation hospital, but it is to be hoped that when Birkenhead possesses a hospital which has some pretence of meeting its needs the authority will do something more than merely touch the fringe of this subject and that they will no longer fine people even 2s a day for going into the hospital for the protection of the public health. According to Mr Vacher, however, matters move very slowly as to this in the borough. Birkenhead is certainly not one of the progressive boroughs in this and other respects but it is not for the want of excellent skilled advice

Cardiff Urban District—The death rate in Cardiff during 1891 was 22.0 per 1000 the zymotic rate being 2.1 Dr Walford enters in much detail into the question of vital statistics and of the distribution, seasonally and otherwise, of diseases belonging to the zymotic group and he illustrates the various points by means of some excellent tables and diagrams He also reports that systematic inspection of the district is maintained, and he points out that new by laws have been obtained as to a number of matters bearing upon public health. Analysis of foods was made in 154 cases and in 13 cases they were found to be adulterated. In each case a fine varying from 10s to £5 was imposed, the smaller fines being in the main imposed in the case of milk supplies, the purity of which is so important to healthy infant life, whilst the larger one was reserved for a margarine case

County of Essex—Dr Thresh has again reviewed and summarised the annual reports of medical officers of health within the administrative county of Essex. The report deals separately with subjects such as death rates, sanitary progress, prevalence of certain diseases &c, and then it gives a summary of each of the reports on the several component sanitary districts A report of this class must have very considerable local value, above all, it affords to the different sanitary authorities concerned a means of comparing the several phases

of sanitary action taken or neglected in different parts of the county and the several results that have ensued.

Northampton Urban District—Mr L. F. Cogan reports that epidemic influenza was a cause of much mortality in Northampton in the early half of 1891, the general rate of mortality being 18.5 per 1000, a rate which exhibited an increase over that for 1890. The zymotic rate was 1.7 per 1000 and the infantile rate 164 per 1000 births. Notification of infectious disease works without difficulty and each intimation of preventable disease is utilised for the purposes of inspection and amendment of faulty sanitary circumstances. A new infectious hospital is now in use, both scarlet fever and enteric fever cases having been under isolation there during the year. Active sanitary work is in progress and an account is given of the action taken in a large number of small streets and courts in the borough. Indeed, 1889 cases were attended to, 969 sets of articles were disinfected and the general activity displayed is evidently having a marked influence upon the health of the town.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

In thirty three of the largest English towns 6194 births and 5775 deaths were registered during the week ending Jan. 7th. The annual rate of mortality in these towns, which had been 20.0 and 24.3 per 1000 in the preceding two weeks, further rose last week to 29.2, a higher rate than in any week since February last. In London the rate was 30.4 per 1000, while it averaged 28.3 in the thirty two provincial towns. The lowest rates in these towns were 18.2 in Croydon, 20.8 in Bristol, 21.6 in Cardiff and 22.0 in Nottingham, the highest rates were 33.6 in Manchester, 34.7 in Leeds, 36.5 in Bolton and 40.5 in Salford. The 5775 deaths included 431 which were referred to the principal zymotic diseases, against 382 and 473 in the preceding two weeks, of these, 134 resulted from measles, 107 from whooping cough, 65 from diphtheria, 64 from scarlet fever, 32 from diarrhoea, 25 from "fever" (principally enteric) and 4 from small pox. No fatal case of any of these diseases occurred last week in Birkenhead or in Huddersfield, in the other towns they caused the lowest death rates in Croydon, Norwich and Wolverhampton, and the highest rates in Bradford, Salford, Preston and Bolton. The greatest mortality from measles occurred in West Ham, Bradford, Hull, Brighton, Derby, Salford, Plymouth and Bolton, from scarlet fever in Burnley and Swansea, and from whooping cough in Leicester, Preston, Birmingham and Salford. The mortality from "fever" showed no marked excess in any of the large towns. The 65 deaths from diphtheria included 47 in London, 4 in Manchester, 3 in Birmingham, 2 in Portsmouth and 2 in Salford. Two fatal cases of small pox were registered in Oldham, 1 in Liverpool and 1 in Halifax, but not one in London or in any other of the thirty three large towns, 38 cases of this disease were under treatment in the Metropolitan Asylum Hospitals on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3121, against 3626, 3299 and 3254 on the preceding three Saturdays, 202 new cases were admitted during the week, against 241 and 246 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 365 to 523 in the preceding three weeks, further rose, under the influence of the recent cold weather, to 953 last week, and exceeded by 264 the corrected average. The causes of 140 or 2.4 per cent., of the deaths in the thirty three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Cardiff, Bolton, Oldham and in six other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Salford, Blackburn, Sheffield and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24.0 and 28.5 per 1000 in the preceding two weeks, declined again to 27.1 during the week ending Jan. 7th, and was 2.2 per 1000 below the mean rate during the same period in the thirty three large English towns. The rates in the eight Scotch towns ranged from 20.7 in Greenock and 24.0 in Perth to 28.6 in Leith and 30.1 in Edinburgh. The 765 deaths in these towns included 79 which were referred to measles, 20 to whooping cough,

17 to scarlet fever, 12 to diarrhoea, 10 to diphtheria, 7 to "fever" and 1 to small pox. In all, 146 deaths resulted from these principal zymotic diseases, against 132 and 131 in the preceding two weeks. These 765 deaths were equal to an annual rate of 5.2 per 1000, which was 3.0 above the mean rate last week from the same diseases in the thirty three large English towns. The fatal cases of measles, which had been 86 in each of the preceding two weeks, declined to 79 last week, of which 32 occurred in Glasgow, 23 in Edinburgh, 9 in Dundee and 7 in Leith. The deaths referred to whooping cough, which had increased from 5 to 17 in the preceding three weeks, further rose to 20 last week and included 16 in Glasgow. The fatal cases of scarlet fever, which had declined from 18 to 7 in the preceding three weeks, rose again to 17 last week, of which 8 occurred in Glasgow, 6 in Edinburgh and 2 in Leith. The 10 deaths from diphtheria slightly exceeded the number in the preceding week and included 4 in Glasgow and 2 in Aberdeen. Of the 7 fatal cases of "fever" 4 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 163 and 212 in the preceding two weeks, further rose last week to 217 and exceeded by 17 the number in the corresponding week of last year. The causes of 83, or nearly 11 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had increased from 22.0 to 33.4 per 1000 in the preceding six weeks, declined again to 31.3 during the week ending Jan. 7th. During the thirteen weeks of the last quarter the death rate in the city averaged 24.4 per 1000 against 18.4 in London and 23.9 in Edinburgh. The 210 deaths in Dublin during the week under notice showed a decline of 14 from the number in the preceding week, and included 11 which were referred to "fever," 3 to measles, 2 to whooping cough, 1 to diarrhoea, and not one either to small pox, scarlet fever, or diphtheria. In all, 17 deaths resulted from these principal zymotic diseases, equal to an annual rate of 2.5 per 1000, the zymotic death rate during the same period being 2.2 in London and 6.6 in Edinburgh. The deaths referred to different forms of "fever," which had been 9 and 4 in the preceding two weeks, rose again to 11 last week, a higher number than has been recorded in any week since December, 1891. The fatal cases of measles, which had been 2 and 1 in the preceding two weeks, rose to 3 last week. The two deaths from whooping cough corresponded with the number in the preceding week. The 210 deaths registered in Dublin last week included 24 of infants under one year of age and 72 of persons aged upwards of sixty years, the deaths of infants showed a slight decline, and those of elderly persons showed a slight further increase upon recent weekly numbers. Five inquest cases and 5 deaths from violence were registered, and 71, or one third, of the deaths occurred in public institutions. The causes of 21, or 10 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1892.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during the month of December in each of the forty one sanitary districts of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases in the accompanying table was equal to 11.0 per 1000 of the population, estimated at 4,263,294 persons in the middle of the year. Owing to the decreasing prevalence of scarlet fever in London this rate showed a further decline from those recorded in the preceding two months, which had been 17.9 and 14.6 per 1000. Amongst the various sanitary districts the rates last month were considerably below the average in Kensington, St. George Hanover square, St. James Westminster, Marylebone, St. Martin in the Fields, St. Olave Southwark, and Woolwich, while they showed the largest excess in Hackney, Clerkenwell, St. George in the East, Limehouse, Mile-end Old Town, Poplar and Plumstead. The prevalence of small pox in London showed a slight further increase during December, 37 cases being notified during the month, against 3, 10 and 32 in the preceding three months, of these 6 belonged to Hackney, 5 to Marylebone, 5 to Camberwell, 3 to Greenwich, and 3 to Whitechapel sanitary areas. The Metropolitan Asylum Hospitals contained

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON — DECEMBER, 1892.
(Specially compiled for THE LANCET.)

Sanitary areas.	Estimated population in the middle of 1892.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths from all causes.	Death rate per 1000 living.	Deaths of infants under one year to 1000 births.

* Including 68 cases of membranous croup.

39 small pox patients at the end of December, against 6 and 20 at the end of the preceding two months, the weekly admissions averaged 10 against 1 and 5 in the previous two months. The prevalence of scarlet fever in London during December showed a considerable further decline from that recorded in recent months, this disease was proportionally most prevalent in Islington, Hackney, Clerkenwell, Bethnal Green, Lambhouse, Mile-end Old Town, Poplar, Newington and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 3168 scarlet fever patients at the end of December, against 3843 and 3754 at the end of the preceding two months, the weekly admissions averaged 254, against 355, 429 and 363 in the previous three months. Diphtheria showed increasing prevalence during the month under notice, this disease was proportionally most prevalent in Paddington, St. Giles, Holborn, Clerkenwell, City of London, Bethnal Green, St. George in the East, Battersea and Plumstead sanitary areas. There were 288 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of December, against 318, 312 and 255 at the end of the preceding three months, the weekly admissions averaged 53, against 54, 57 and 48 in the previous three months. Enteric fever was proportionally most prevalent during December in St. George Hanover square, Westminster, Hampstead and Poplar. The Metropolitan Asylum Hospitals contained 87 enteric fever patients at the end of December, against 124 and 113 at the end of the preceding two months, the weekly admissions averaged 12, against 15 in each of the previous two months. Erysipelas showed the highest proportional prevalence in St. Pancras, St. Luke, Mile end Old Town, Poplar, Greenwich and Lewisham sanitary areas. Five cases of puerperal fever were notified during December in St. Pancras, 4 in Hackney, 3 in Kensington, 3 in Fulham, 3 in Poplar and 3 in Wandsworth sanitary districts.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary districts, the deaths occurring in the institutions of London having been distributed amongst the various sanitary districts in which the patients had previously resided. The distribution of these deaths, and especially of those resulting from zymotic diseases, affords the most trustworthy data that can be secured upon which to calculate reliable rates of mortality. During the four weeks ending on Saturday, Dec. 31st, the deaths of 6364 persons belonging to London were registered, equal to an annual rate of 19.5 per 1000, against 15.7, 17.1 and 17.9 in the preceding three months. The lowest death rates during December in the various sanitary districts were 11.8 in Hampstead, 15.1 in Wandsworth, 15.0 in St. James Westminster, 15.6 in Kensington, 15.7 in Lewisham (excluding Penge), 15.9 in Hammersmith and 16.1 in Chelsea, in the other sanitary districts the rates ranged upwards to 24.1 in Clerkenwell, 24.6 in Holborn, 24.7 in Newington, 24.8 in St. George Southwark, 25.0 in St. George in the East, 25.5 in St. Olave Southwark, and 26.3 in the Strand. During the four weeks of December 667 deaths were referred to the principal zymotic diseases in London, of these, 224 resulted from diphtheria, 141 from measles, 104 from scarlet fever, 90 from whooping cough, 58 from diarrhoea, 49 from different forms of "fever" (including 48 from enteric fever and 1 from an ill defined form of continued fever) and 1 from small pox. These 667 deaths were equal to an annual rate of 2.0 per 1000, against rates declining from 3.9 to 1.8 in the preceding five months. Amongst the various sanitary districts the lowest zymotic death rates were recorded in Kensington, Hammersmith, St. James Westminster, Hampstead, Holborn, St. Olave Southwark, and Bermondsey, and the highest rates in St. Giles, Bethnal Green, St. George in the East, Poplar, Rotherhithe, Greenwich and Plumstead. Only 1 fatal case of small pox was registered in London during the month under notice, the corrected average number in the corresponding period of the preceding ten years being 18, this case belonged to St. George in the East sanitary district. The 141 deaths referred to measles were rather less than half the average, among the various sanitary districts this disease showed the highest proportional fatality in Bethnal Green, Poplar, Rotherhithe, Greenwich and Plumstead. The 104 fatal cases of scarlet fever were 6 below the corrected average, this disease was proportionally most fatal in Fulham, St. George in the East and Battersea sanitary districts. The 224 deaths referred to diphtheria were more than double the corrected average, this disease showed the highest proportional fatality in St. Giles, Clerkenwell, City of London, Bethnal Green, St. George in the East, Mile-end Old Town,

Newington and Plumstead sanitary districts. The 90 fatal cases of whooping cough were 123 below the corrected average, this disease was somewhat fatally prevalent in Newington, Battersea and Lewisham. The 49 deaths referred to different forms of "fever" were 25 below the corrected average, there was no marked excess of "fever" mortality in any of the sanitary districts during the month under notice. The 58 deaths from diarrhoea almost corresponded with the average. In conclusion, it may be stated that the mortality in London during December from these principal zymotic diseases in the aggregate was as much as 24 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 145 per 1000, and was considerably below the average, the lowest rates of infant mortality were recorded in Westminster, St. Martin in the Fields, St. Luke, St. Saviour Southwark, Bermondsey and Plumstead, the highest rate in St. James Westminster, St. Giles, Strand, Holborn, St. George Southwark, and St. Olave Southwark.

THE SERVICES

MOVEMENTS OF MEDICAL STAFF

SURGEON COLONEL PRESTON has embarked for Hong Kong to succeed Surgeon Colonel Paterson in the Administrative Medical Charge. Surgeon Lieutenant Colonel A. Retired List, has been appointed to the Medical Charge of Fleetwood. Surgeon Major Green has resumed his duties in Burma, after leave of absence in England, and Surgeon Major Carleton has arrived in Bombay on return from sick leave. Brigade Surgeon Scott has relinquished the half pay appointment at Sheffield. Surgeon Major Lane has been taken on the strength of the Portsmouth district. Surgeon Captains James and Westcott have arrived at Hong Kong on a tour of service. Surgeon Lieutenant Colonel Finlay has been transferred from Hounslow to Sherness. Surgeon Captain Cockerill has arrived in India on return from sick leave. Surgeon Captain Salvage has joined for duty at Woolwich, Surgeon Captain Philson at Aldershot, Surgeon Captain Greig at Dover and Surgeon Captain Squire at Shoeburyness.

ARMY MEDICAL STAFF

Surgeon Major Charles Bere, Medical Staff Corps, to Quartermaster, with the honorary rank of Lieutenant in Honorary Captain W. McKay, retired on temporary half pay (dated Jan 11th, 1893).

INDIA AND THE INDIAN MEDICAL SERVICE.

The following appointments have been made.—2nd Bengal Infantry Surgeon Lieutenant-Colonel T. Robinson, from the Medical Charge of the 1st Battalion 1st Gurkha Rifles to the Officiating Medical Charge of the Regiment. 4th Bengal Infantry Surgeon Captain E. Jennings to the Officiating Medical Charge of the Regiment, vice Surgeon Captain B. Basu. 5th Bengal Light Infantry Surgeon Captain C. N. Wimberley to the Officiating Medical Charge of the Regiment, vice Surgeon Captain U. N. Mukerji. 2nd Bengal Light Infantry Surgeon Lieutenant-Colonel T. Robinson from the Officiating to the Medical Charge of the Regiment, vice Surgeon Major G. A. Cones, retired. 14th Sikhs Surgeon Captain W. H. E. Woodwright to the Officiating Medical Charge of the Regiment, vice Surgeon Captain W. M. Lau. 16th Bengal Infantry Surgeon Captain B. C. Oldham from the Officiating Medical Charge of the 2nd Bengal Light Infantry to the Officiating Medical Charge of the Regiment, vice Surgeon Captain E. R. W. C. Carroll. 31st Punjab Infantry Surgeon Captain B. J. Singh, to the Officiating Medical Charge of the Regiment, vice Surgeon Captain J. G. Jordan. 34th Pioneer Regiment Surgeon Captain E. W. Hore to the Officiating Medical Charge of the Regiment, vice Surgeon Captain W. H. B. Robinson. 7th Regiment Madras Infantry Surgeon Lieutenant W. E. Armstrong, I.M.S., to the Officiating Medical Charge of the Regiment. Surgeon Lieutenant-Colonel M. Knox, I.M.S., Ranikhet, is appointed to hold Charge of the Civil Medical duties of Ranikhet in addition to his military duties from Nov 19th, 1892. 18th Bengal Infantry Surgeon Captain J. C. S. Vaughan to the Officiating Medical Charge of the Regiment, vice Surgeon Captain J. F. Evans. The mentioned officer has been granted permission to return duty.—Surgeon Lieutenant-Colonel R. A. Holmes, I.M.S., Superintendent, Central Prison, Lucknow. The services

Surgeon Captain R. J. Baker, M.A., M.D., have been placed at the disposal of the Government of India in the Foreign Department. Veterinary Captain F. J. Short has been appointed to the Civil Veterinary Department on probation and posted to the Central Provinces and Berar. Surgeon-Major J. C. Marsden has been appointed Civil Surgeon Negrapatam, in succession to Surgeon-Major Bain. Surgeon Captain A. Buchanan, Superintendent of the Raurpur Central Gaol, has been appointed to the Charge of the Nagpur Central Gaol. Surgeon P. W. O'Gorman, I.M.S., Bengal Establishment Medical Officer of the Mushkof Bolan State Railway, has been transferred from the P. W. Department to the Home Department. Surgeon Lieutenant Colonel A. A. MacRobin assumed Charge of the Civil Medical duties of Kasauli on the forenoon of Dec. 2nd, 1892, relieving Surgeon Lieutenant Colonel M. D. O'Connell. Surgeon Captain E. D. Brighurst-Farmar, A.M.S. has been granted an extension of leave from Dec. 7th 1892 to June 6th 1893 on medical certificate.

NAVAL MEDICAL SERVICE.

The following appointments have been made—Staff Surgeons Myles O. C. McSwiney to the *Eagle* (dated Jan. 5th 1893) and J. A. Collet to the *Collingwood* (undated). Surgeons Evan St. M. Nepean to the *Minotaur* (dated Jan. 5th, 1893), John H. Stenhouse to the *Collingwood* (undated), James M. France to the *Swiftsure* (dated Jan. 11th, 1893). Surgeon and Agent Thomas W. Fairman at Lyttelton New Zealand and James B. Lawson, M.D., at Rothesay (both dated Jan. 2nd, 1893).

YEOMANRY CAVALRY.

Hampshire (Carabiniers) Surgeon Lieutenant G. F. A. England, M.B. to be Surgeon Captain (dated Jan. 7th, 1893).

VOLUNTEER CORPS.

Engineer 1st West Riding of Yorkshire (Sheffield) Thomas Stewart Adair, M.B., to be Surgeon-Lieutenant (dated Jan. 7th, 1893)—*Rifle* 2nd Volunteer Battalion, the Gloucestershire Regiment. Honorary Assistant Surgeon C. W. Morris resigns his commission (dated Jan. 7th, 1893)—1st Volunteer Battalion Princess Charlotte of Wales (Royal Berkshire Regiment) Surgeon Captain J. H. Walters resigns his commission (dated Jan. 7th 1893)—2nd Volunteer Battalion, the Duke of Edinburgh's (Wiltshire Regiment) Surgeon Major E. N. Carless to be Surgeon Lieutenant-Colonel (dated Jan. 7th, 1893).

INFANTRY VOLUNTEER BRIGADE.

Manchester Brigade Surgeon-Captain Duncan, M.B., 3rd Volunteer Battalion the Manchester Regiment, to be Brigade-Surgeon Lieutenant-Colonel (dated Jan. 7th, 1893).

OBITUARY.

Brigade Surgeon J. Wallace, Retired List, Army Medical Staff, died at Hotel des Palmiers, Nice, on the 22nd ult. He joined the Army June 2nd 1857, became Surgeon, March 1st, 1873, Surgeon-Major, April 1st, 1873, and retired with the honorary rank of Brigade-Surgeon May 30th, 1885. He served in the Afghan War of 1878-79 (medal) and also in the Sudan Expedition, under Sir Gerald Graham in 1884 (medal and Khedive's star).

THE NEW ROYAL WARRANT.

We understand that the privilege of counting twelve months of half pay towards retirement lately conferred by Royal Warrant is to be enjoyed by all officers on the full pay list at the time of its promulgation. The effect of this is that every officer now serving will benefit by the concession, whether he was on half pay prior to the issue of the Warrant or not.

SURGEON COLONEL PRESTON, P.M.O.

The officers of the Medical Staff, Belfast district, entertained Surgeon Colonel Preston, P.M.O. at dinner on the 28th ult., at the Royal Avenue Hotel, prior to his departure for Hong Kong, he having been selected for the appointment of Principal Medical Officer of the China Station. The following were amongst those invited or present—Major General Godfrey Clerk, C.B., Surgeon Major General J. Sinclair, Col. O. Grady Haly, D.S.O., A.A.G., Colonel Dawson, 83rd Regimental District, Lieutenant-Colonel Glencross, 1st Lancashire Fusiliers, Lieutenant Colonel Parker R.E., Lieutenant-Colonel St. Paul, 2nd Rifle Brigade, Brigade-Surgeon M. Farland, Lieutenant-Colonel Chalice, A.S. Corps, Lieutenant Colonel Brereton, A.P.D., Major V. Johnson, D.A.A.G., Major Holland 15th H.A.S.s., Mr. Bond, Medical Staff Corps, Dr. Walton Browne, President North of Ireland Branch British Medical Association, and Dr. Whitaker President Ulster Medical Society.

MEDICAL EXAMINATION OF MILITIA OFFICERS.

Successful candidates for commissions in the army will in future be inspected by a medical board after the competitive examination and no candidate will be considered eligible for a commission unless certified by the board to be physically fit in all respects for Her Majesty's service.

THE HURDWAR FAIR.

The Government of the North Western Provinces and Oudh has appointed a committee to examine and report on the sanitary conditions of Hurdwar on the occasions of the great bathing fairs consisting of the Sanitary Commissioner to the Local Government as president with an engineer officer of experience and the magistrate of Saharanpur and associated with these officials five Hindu gentlemen who have been requested to aid the Government with their advice. This is a wise policy to adopt and we trust that measures will be devised for making the sanitary and other arrangements for these fairs satisfactory—especially in the way of securing a good water supply for potable purposes and fresh running water for the bathing place of the pilgrims. Arrangements against overcrowding and fouling of the surface soil are also required, together with power to break up and disperse the assembly in case of need.

THE NEW GERMAN ARMY BILL.

This continues to excite great attention in Germany and on the Continent generally. During the last twenty years the cost of military defences in Europe has nearly doubled and the enormous expenditure under which the nations are groaning can scarcely be increased further—indeed, the wonder is how it can be borne, and how it is proposed to find the number of medical officers that will be required if these forces ever come into collision armed as they are with quick-firing rifles and arms of precision. This great increase of European armies has taken place since the termination of the Franco-German War, and the loss of Alsace-Lorraine by the French naturally gave rise to the enormous increase of their army, which is now said to number 4,350,000 men. If the new Army Bill passes the German army will in a few years have a strength of 5,000,000. The strongest military Power in Europe, however is Russia, which has at its disposal 6,000,000 soldiers to carry out a policy which can scarcely be described as one of peace and goodwill to men.

THE RUPEE AND INDIAN SERVICE.

Service in India is not very popular at the present time and medical officers are not likely to be attracted to that country by the emoluments it offers. The fallen and still falling rupee has become a serious question, meetings are being held in the large cities of India—by the Bombay branch of the Indian Currency Association, for example—at which resolutions are passed for petitioning the Government of India to urge the Secretary of State to sanction the immediate closing of the mints for the coinage of silver as the only prompt way of relieving the Government of its financial troubles. India, it is urged, is the only country where the mints are open to an unrestricted coinage of silver.

Audi alteram partem.

"THE LATE DR. WALSHÉ"

To the Editors of THE LANCET

SIR—It would be a pity if no voice were to go forth from Scotland as a tribute to the late Dr. Walshé, and although it may be in one sense a superfluity to praise where all are of one mind, yet you will perhaps allow me a few lines to echo as it were the voices of your English correspondents. My acquaintance with Dr. Walshé (no doubt far less intimate than theirs) goes back a long way—to the time, in fact, when he was still a clinical teacher in University College Hospital and just emerging into consulting practice, in the presence of such men as Watson, Latham and C. J. B. Williams. Even in these days I can distinctly recall the impression on my own mind as an outsider (so to speak) in London professional circles that in precision of method and fulness of individual information Dr. Walshé was difficult to surpass and I think I should have placed him even then first

39 small pox patients at the end of December, against 6 and 20 at the end of the preceding two months, the weekly admissions averaged 10, against 1 and 5 in the previous two months. The prevalence of scarlet fever in London during December showed a considerable further decline from that recorded in recent months, this disease was proportionally most prevalent in Islington, Hackney, Clerkenwell, Bethnal Green, Limehouse, Mile-end Old Town, Poplar, Newington and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 3168 scarlet fever patients at the end of December, against 3843 and 3754 at the end of the preceding two months, the weekly admissions averaged 254, against 355, 429 and 363 in the previous three months. Diphtheria showed increasing prevalence during the month under notice, this disease was proportionally most prevalent in Paddington, St. Giles, Holborn, Clerkenwell City of London, Bethnal Green, St. George in the East, Battersea and Plumstead sanitary areas. There were 288 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of December, against 318, 312 and 255 at the end of the preceding three months, the weekly admissions averaged 53, against 54, 57 and 48 in the previous three months. Enteric fever was proportionally most prevalent during December in St. George Hanover square, Westminster, Hampstead and Poplar. The Metropolitan Asylum Hospitals contained 87 enteric fever patients at the end of December, against 124 and 113 at the end of the preceding two months, the weekly admissions averaged 12, against 15 in each of the previous two months. Erysipelas showed the highest proportional prevalence in St. Pancras, St. Luke, Mile-end Old Town, Poplar, Greenwich and Lewisham sanitary areas. Five cases of puerperal fever were notified during December in St. Pancras, 4 in Hackney, 3 in Kensington, 3 in Fulham, 3 in Poplar and 3 in Wandsworth sanitary districts.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary districts, the deaths occurring in the institutions of London having been distributed amongst the various sanitary districts in which the patients had previously resided. The distribution of these deaths, and especially of those resulting from zymotic diseases, affords the most trustworthy data that can be secured upon which to calculate reliable rates of mortality. During the four weeks ending on Saturday, Dec 31st, the deaths of 6364 persons belonging to London were registered, equal to an annual rate of 19.5 per 1000 against 15.7, 17.1 and 17.9 in the preceding three months. The lowest death rates during December in the various sanitary districts were 11.8 in Hampstead, 15.1 in Wandsworth, 15.0 in St. James Westminster, 15.6 in Kensington, 15.7 in Lewisham (excluding Penge), 15.9 in Hammersmith and 16.1 in Chelsea, in the other sanitary districts the rates ranged upwards to 24.1 in Clerkenwell, 24.6 in Holborn, 24.7 in Newington, 24.8 in St. George Southwark, 25.0 in St. George in the East, 25.5 in St. Olave Southwark, and 26.3 in the Strand. During the four weeks of December 667 deaths were referred to the principal zymotic diseases in London, of these, 224 resulted from diphtheria, 141 from measles, 104 from scarlet fever, 90 from whooping cough, 58 from diarrhoea, 49 from different forms of 'fever' (including 48 from enteric fever and 1 from an ill defined form of continued fever) and 1 from small pox. These 667 deaths were equal to an annual rate of 2.0 per 1000, against rates declining from 3.9 to 1.8 in the preceding five months. Amongst the various sanitary districts the lowest zymotic death rates were recorded in Kensington, Hammersmith, St. James Westminster, Hampstead, Holborn St. Olave Southwark, and Bermondsey, and the highest rates in St. Giles, Bethnal Green, St. George in the East, Poplar, Rotherhithe, Greenwich and Plumstead. Only 1 fatal case of small pox was registered in London during the month under notice, the corrected average number in the corresponding period of the preceding ten years being 18, this case belonged to St. George in the East sanitary district. The 141 deaths referred to measles were rather less than half the average, among the various sanitary districts this disease showed the highest proportional fatality in Bethnal Green, Poplar, Rotherhithe, Greenwich and Plumstead. The 104 fatal cases of scarlet fever were 6 below the corrected average, this disease was proportionally most fatal in Fulham, St. George in the East and Battersea sanitary districts. The 224 deaths referred to diphtheria were more than double the corrected average, this disease showed the highest proportional fatality in St. Giles, Clerkenwell City of London, Bethnal Green, St. George in the East, Mile-end Old Town,

Newington and Plumstead sanitary districts. The 90 fatal cases of whooping cough were 128 below the corrected average, this disease was somewhat fatally prevalent in Newington, Battersea and Lewisham. The 49 deaths referred to different forms of 'fever' were 25 below the corrected average, there was no marked excess of 'fever' mortality in any of the sanitary districts during the month under notice. The 58 deaths from diarrhoea almost corresponded with the average. In conclusion, it may be stated that the mortality in London during December from these principal zymotic diseases in the aggregate was as much as 24 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 145 per 1000, and was considerably below the average, the lowest rates of infant mortality were recorded in Westminster, St. Martin in the Fields, St. Luke, St. Saviour Southwark, Bermondsey and Plumstead, the highest rates in St. James Westminster, St. Giles, Strand, Holborn, St. George Southwark, and St. Olave Southwark.

THE SERVICES

MOVEMENTS OF MEDICAL STAFF

SURGEON COLONEL PRESTON has embarked for Hong Kong to succeed Surgeon Colonel Paterson in the Administrative Medical Charge. Surgeon Lieutenant Colonel Ash, Retired List, has been appointed to the Medical Charge at Fleetwood. Surgeon Major Green has resumed his duties in Burma, after leave of absence in England, and Surgeon Major Carleton has arrived in Bombay on return from sick leave. Brigade Surgeon Scott has relinquished the half-pay appointment at Sheffield. Surgeon Major Lane has been taken on the strength of the Portsmouth district. Surgeon Captains James and Westcott have arrived at Hong Kong on a tour of service. Surgeon Lieutenant-Colonel Finlay has been transferred from Hounslow to Sherness. Surgeon Captain Cockerill has arrived in India on return from sick leave. Surgeon Captain Salvage has joined for duty at Woolwich, Surgeon Captain Philson at Aldershot, Surgeon Captain Greig at Dover and Surgeon Captain Squire at Shoeburyness.

ARMY MEDICAL STAFF

Surgeon Major Charles Bere, Medical Staff Corps, to be Quartermaster, with the honorary rank of Lieutenant, vice Honorary Captain W. McKay, retired on temporary half pay (dated Jan 11th, 1893).

INDIA AND THE INDIAN MEDICAL SERVICE

The following appointments have been made.—2nd Bengal Infantry. Surgeon Lieutenant Colonel T. Robinson, from the Medical Charge of the 1st Battalion 1st Gurkha Rifles to the Officiating Medical Charge of the Regiment. 4th Bengal Infantry. Surgeon Captain E. Jennings to the Officiating Medical Charge of the Regiment, vice Surgeon Captain B. K. Basu. 5th Bengal Light Infantry. Surgeon Captain C. N. C. Wimberley to the Officiating Medical Charge of the Regiment, vice Surgeon Captain U. N. Mukerji. 2nd Bengal Light Infantry. Surgeon Lieutenant Colonel T. Robinson from the Officiating to the Medical Charge of the Regiment, vice Surgeon Major G. A. Cones, retired. 14th Sikhs. Surgeon Captain W. H. E. Woodwright to the Officiating Medical Charge of the Regiment, vice Surgeon Captain W. M. Lane. 16th Bengal Infantry. Surgeon Captain B. C. Oldham from the Officiating Medical Charge of the 2nd Bengal Light Infantry to the Officiating Medical Charge of the Regiment, vice Surgeon Captain D. R. W. C. Carroll. 31st Punjab Infantry. Surgeon Captain B. J. Singh, to the Officiating Medical Charge of the Regiment, vice Surgeon Captain J. G. Jordan. 34th Pioneers. Surgeon Captain E. W. Hore to the Officiating Medical Charge of the Regiment, vice Surgeon Captain W. H. B. Robinson. 7th Regiment Madras Infantry. Surgeon Lieutenant W. E. Armstrong, I.M.S., to the Officiating Medical Charge of the Regiment. Surgeon Lieutenant Colonel M. Knox, M.S. Ranikhet, is appointed to hold Charge of the Civil Medical duties of Ranikhet in addition to his military duties from Nov 19th, 1892. 18th Bengal Infantry. Surgeon Captain J. C. S. Vaughan to the Officiating Medical Charge of the Regiment, vice Surgeon Captain J. F. Evans. The under mentioned officer has been granted permission to return to duty.—Surgeon Lieutenant-Colonel R. A. K. Holmes, I.M.D. Superintendent, Central Prison, Lucknow. The services

new buildings connected with the Royal Infirmary, Aberdeen, are completed Professor Cash, the Teacher of Materia Medica and Therapeutics in the University of Aberdeen, is to have wards handed over to him. This demonstrates that the Aberdeen medical faculty is alive to its interests, and Glasgow University will soon, perhaps be the only great medical school in the kingdom so ingloriously unique in its abnormality as regards therapeutics.

I am, Sirs, your obedient servant

JAMES W. CLELAND, Hon. Sec.

Glasgow University Students' Representative Council, Jan. 10th, 1893.

HOSPITALS AS CENTRES OF STUDY

To the Editors of THE LANCET

SIRS,—We have throughout England many towns containing hospitals to which are attached post-mortem rooms. Grouped round each hospital as a centre are town and suburban practices, the principals of which are appointed officers of the hospital. Outside these come groups of country practices. It would be a great boon to practitioners and the public also if more use could be made of these hospitals as centres of study, especially as regards surgery. It would cost but little trouble to arrange courses of operative surgery on the dead body if clinical societies of the various towns would take up the matter. The chief obstacle would be public opinion, and I believe that great and influential organs like THE LANCET could, if they thought fit, educate public started by itself the public of that district would probably opinion. If many centres agreed simultaneously to take up the matter much good might be done. But if only one centre make up what it calls its mind and stamp out an honest endeavour to improve the skill and worth of its own medical advisers. Hoping that some of your readers may express an opinion on this idea, I remain, Sirs, yours truly,
Jan. 8th, 1893. L.R.C.P., M.R.C.S.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Hospital Sunday

LAST Sunday was the twenty third anniversary of Hospital Sunday in Liverpool, the first being observed on Jan. 8th, 1871. The second Sunday in the year was after due consideration agreed upon by the local clergy and ministers as the day on which the collections should be made. For the first few years the weather on Hospital Sunday was remarkably good and the collections realised sums rising from £4685 in 1871 to £8848 in 1874. This was the maximum sum raised in church and chapel collections, the following years showing fluctuations, whether owing to the inclement weather or to the depression of trade, or to both, it would be difficult to say. But the fact remains that the lowest sum raised by this means since 1874 was £6029 in 1887, which gradually improved to £6973 in 1891. Last year there was again a falling off and great efforts have been made to prevent its repetition this year. The weather was most inclement, but while some of the collections show a decrease, an almost equal number show an increase over the sum collected last year. The mayor, Mr R. D. Holt, attended in state the Renshaw street Unitarian Chapel, of which congregation he has been a member for many years past. After an eloquent sermon by the Rev J. P. Jacks a collection was made which amounted to the magnificent sum of £709 9s. 8d. Many other handsome collections are announced, but it would be premature to attempt any estimate of the total at present.

Action against a Cafe Company

In October last a case was before the Court of Passage in which the plaintiff, an inspector of agents in a life insurance company, sued the representatives of the Clerks' Cafe Company for compensation for illness alleged to be caused by the defendants supplying him with bad food at the Economic Cafe. The jury disagreed in consequence of which the case was again heard on the 5th and 6th inst. The plaintiff partook of curried steak and stewed rhubarb on June 27th, 1892. He was immediately seized with violent vomiting and diarrhoea and felt strange in his head. From this date till Sept 5th no solid food would stay on his stomach. During all this time he was under medical treatment and lost about three stones in weight. On his behalf medical evidence was given to the

effect that the symptoms might be due to putrid meat. For the defence it was contended that none but wholesome meat was supplied to the defendants' cafes, of which they had eight. Medical evidence given for the defendants was to the effect that the symptoms occurred too rapidly to be the result of eating putrid meat. The jury returned a verdict for the defendants.

Small-pox and Revaccination

Although small-pox prevails both in Manchester and Warrington, between both of which towns and Liverpool there is constant communication, the disease has not made any advance here, any cases that may occur being promptly removed to hospital. The prosecution of the two women (noticed in a previous letter) for concealing the disease has had a very wholesome effect in not only deterring others from doing the same, but in showing all the advantage of working with, not against, the sanitary officers. The select committee who regulate the affairs of the parish of Liverpool afford every facility to those who desire to be revaccinated.

Insanitary Property in Liverpool

On the 7th inst. Mr Walton, Q.C., M.P. the arbitrator appointed by the Local Government Board to consider the claims for compensation made in regard to property which had been declared to be insanitary, concluded his inquiry. As a proof of the propriety of "presenting" the property in question, it may be mentioned that one man claimed in respect of twelve houses in two courts of two streets. The property was freehold and comprised 575 square yards. It was alleged to be insanitary because of the absence of water-closet accommodation, but the claimant contended that this difficulty could be got over by means of structural alterations. The gross rental was given as £95 and the net rental as £46, but the claimant declined to produce his rent-book. Dr Taylor, medical officer of health for Liverpool, Dr Hope, assistant medical officer of health, and Dr Littlejohn of Edinburgh had all condemned the houses as insanitary and as incapable of being made sanitary. The arbitrator's award will be forwarded to the town clerk.

Taking the Oath with Uplifted Hand

A copy of the resolutions passed at the last ordinary meeting of the Liverpool Medical Institution is published in each of the three local daily papers. One of them, the *Liverpool Mercury*, warmly encourages the new mode of oath taking, and suggests that all similar organisations of the faculty should follow the example set by the Liverpool Medical Institution. At the trial in the Court of Passage mentioned above the first medical witness, Dr Smart, declined the book and claimed to be sworn with uplifted hand, which was at once done. His example was followed by all the other medical witnesses, Drs Nisbet and Hushy, Professor Paul, Drs Mann and Taylor, and Mr Vacher. These gentlemen deserve great credit for giving such prompt effect to the resolutions alluded to, and it is now to be hoped that the practice of kissing the book will rapidly become a thing of the past.

January 11th.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Small-pox in the Northern Counties

THE introduction of small pox by tramps and casuals is giving our authorities much concern. Cases have occurred and have spread in this way at Sunderland and Newcastle workhouses. In Durham city, too cases have been reported and, indeed, all over the county of Durham the disease has got a footing.

Lecture on Pedigrees by Professor Milnes Marshall

Dr Milnes Marshall, Professor of Zoology in Owens College, Manchester, delivered an admirable lecture in Newcastle this week on Pedigrees. He illustrated some of his theories by familiar animals such as the horse, which he said is descended from a prehistoric animal with five fingers or toes on each leg now represented by the hoof, but the splints, he said, were the representatives of the four other toes which had disappeared, but were still shown in fossil equine animals.

The Bones Museum at Barnard Castle

I am sorry to say that at a meeting of the trustees and executors of the will of Benoit Josephine Bowes, Countess of Montalto held lately they decided to close the splendid museum and park at Barnard Castle to the public, except

amongst English auscultators. In view of the successive editions of his (now subdivided) works on the heart and the lungs respectively, there will be few, I think, who will now question this precedence. In spite of a tendency to over refinement, which makes it more difficult, perhaps, apart from the personal traditions of his teaching, to recommend these works to students, I have always placed them in the very front rank, giving explanations in detail where the difficulties come in, or where I fancy they come in, so as to be perplexing to students not bred in University College traditions or by Dr Walshe's own pupils. This explained, Dr Walshe's books are even now better worth studying in many respects than any of their more modern rivals, and certainly beyond all comparison superior in impartiality and breadth of view to Skoda's running commentaries on Laennec. The curious anecdote by Dr Wilks in THE LANCET of to-day goes to show that, with all his admiration for Louis as his early teacher and his high estimate of the numerical method Dr Walshe was fully alive to the limitations of the method and regarded it, as many of us now are disposed to regard the "pre Raphaelite" school in art, as only a "stepping stone to higher things." My personal opportunities of meeting Dr Walshe occurred at such rare and distant intervals that the sum of them does not come to much, but I can well understand and appreciate all that is said of him from the higher point of view of his character and genius. Dr Walshe's was not, however, the genius that scornfully rejects details or aims at posing in an attitude of mental superiority. He was *naturæ minister et interpres*, but chiefly and, above all, the latter.

I am, Sirs, yours truly,

Glasgow, Jan. 7th, 1893. W T GAIRDNER, LL.D., M.D. Edin.

BICARBONATE OF POTASH IN INFLUENZA

To the Editors of THE LANCET

SIRS,—In your "Annus Medicus 1892," under the heading "Therapeutic Progress," the following sentence occurs: "Influenza in the earlier part of the year, and cholera in the autumn, produced a crop of specifics of which little need be said beyond noting that the efficacy claimed for them was, as usual, greatest during the decline of the epidemics." The writer seems to convey the impression that no progress worth noting has been made during 1892 in the treatment of influenza and cholera. I demur to the accuracy of this statement in the case of influenza. Three years ago, by a process of reasoning from facts placed at my disposal (as at the disposal of all) by the most reliable living bacteriologists, I hoped that I had found an effectual and speedy remedy for influenza. On July 16th, 1891, I communicated my discovery to the members of the Border Counties Branch of the British Medical Association in an address which, as president, my position imposed upon me.

An abstract of my address appeared in THE LANCET on Dec 19th, 1891. I naturally watched the subsequent issues with expectancy, but the article seemed to me at the time to have fallen flat and to have arrested very little attention, however, it was not quite so, as I afterwards found out. You very liberally published a leader in THE LANCET of Jan 23rd, 1892, calling the attention of the profession to my conclusions but declining insertion of the evidence I adduced as to the value of my remedy. The bold, fearless and fair statements in that leader more than atoned for the airs of superiority assumed by the writer. One of the best known and most respected teachers in the University of Edinburgh had previously stated, from personal knowledge, his full conviction of the thoroughly satisfactory character of the new treatment. I give his *ipsissima verba* from his letter now lying before me: "My strength never suffered, and indeed my rapid recovery and immunity from all of the unpleasant after consequences of influenza made it somewhat difficult for me to believe that I had actually successfully combated an affection which has led to such consequences in some of its victims. However, there can be no doubt about the correctness of the diagnosis, the value of your remedy, or the satisfactory results of its energetic use." In the most manly and straightforward manner he has given me leave to make use of his name and experience in support of my contention. I refer to Dr David Hepburn, F.R.S. Edin. &c. Out of the many communications which you must have received in response to your invitation, some from gentlemen well qualified from practical experience to form a reliable opinion, there were some which you did not insert. But I assume, acting on your editorial judgment, that the two letters you printed

—the only letters that referred to me by name—were fairly representative of your correspondents, placing before the profession the general sense of their experience. Those letters were confirmatory of my position. Mr Pugin Thornton of Canterbury (THE LANCET, Jan. 30th, 1892, page 279), a well known medical author, a valued contributor to Sir Richard Quain's Dictionary of Medicine, and a man of ripe experience and acute observation, says: "During this epidemic I have used nothing else but bicarbonate of potash, giving it, as recommended by Mr Crerar, in half drachm doses in milk every three hours as long as the fever lasted. Last epidemic I gave salicylate of soda with bromide of ammonium, after an injection of apomorphia or an aperient, and the bicarbonate treatment I find by far the best." This was not "during the decline of the epidemic," as asserted in your summary of Dec 31st, 1892, but during the whole of the second epidemic from its commencement up to that date, and Mr Thornton draws a careful comparison between my treatment and the accredited treatment previously used, entirely to my advantage. I needed not Mr Thornton's testimony, valuable as it is, to establish my contention.

"It only serves to thicken other proofs
That do demonstrate (by no means) thinly."

To any person reasonably open to conviction the evidence already placed before the profession is quite conclusive. I further affirm most emphatically that it was in severe cases and in the acute stages of the epidemic that the value of my treatment was most conspicuous. Also let me not be misapprehended. The patient ought to be under the care of his physician, who will adopt the usual precautionary measures in such cases, but the bicarbonate will be his sheet-anchor. Furthermore, as I intend when leisure serves to write a monograph on this subject, in which my views on the etiology, pathology and treatment of influenza will be fully expressed, unfettered by the limitations necessarily imposed on an article in a weekly journal, I will not trespass further on your valuable space. Meantime, as I have been singled out in your Annus Medicus for a thinly veiled attack, I have confidence that you will in common fairness give me the opportunity of defending myself by inserting this *apologia pro medicina mea*. I am, Sirs, yours truly

JOHN CRERAR, M.R.C.P. Edin.

** We have been compelled to abbreviate Mr Crerar's letter, but we think he is mistaken in supposing that we have received many communications on this subject. To the best of our recollection the letters referred to by him as being inserted in our columns were all that were received by us. We might also point out that the summary to which he takes exception refers to the year 1892 and not 1891, when he first drew attention to the efficacy of bicarbonate of potash in influenza. He must know that many other drugs have been alleged to be of specific action in this disease by other writers in this country and abroad. We shall await his projected monograph with interest.—ED. L.

THE TEACHING OF THERAPEUTICS AT GLASGOW

To the Editors of THE LANCET

SIRS,—At the last meeting of the Glasgow University Students Representative Council Mr de Hyde-Wyatt submitted the following motion: "That in view of the change in the Medical Ordinance—which now reads *Materia Medica* and *Therapeutics* instead of the old reading, *Materia Medica* and *Pharmacy*—that a deputation wait upon the Senate requesting them to ask the managers and directors of the Western Infirmary to place wards at the disposal of the Professor of *Materia Medica* and *Therapeutics* in the University of Glasgow in order that he may be able to give full and proper instruction in that most highly important of the medical sciences—therapeutics, the art and science of healing." This was carried unanimously and referred to the Grand Committee in Medicine to take proper steps. As the result the latter body elected a deputation which will wait upon the Senate as soon as possible and ask their cooperation in rectifying the anomalous state of affairs which obtains that Dr M. Charters, the Professor of *Materia Medica* and *Therapeutics*, having no wards at his disposition can only teach therapeutics in the lecture room. This is preposterous for this subject is pre eminently a practical one. When the

new buildings connected with the Royal Infirmary, Aberdeen, are completed Professor Cash, the Teacher of Materia Medica and Therapeutics in the University of Aberdeen, is to have wards handed over to him. This demonstrates that the Aberdeen medical faculty is alive to its interests, and Glasgow University will soon, perhaps, be the only great medical school in the kingdom so ingloriously unique in its abnormality as regards therapeutics.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

Hospital Sunday

LAST Sunday was the twenty-third anniversary of Hospital Sunday in Liverpool, the first being observed on Jan. 8th, 1871. The second Sunday in the year was after due consideration agreed upon by the local clergy and ministers as the day on which the collections should be made. For the first few years the weather on Hospital Sunday was remarkably good and the collections realised sums rising from £4685 in 1871 to £8848 in 1874. This was the maximum sum raised in church and chapel collections, the following years showing fluctuations whether owing to the inclement weather or to the depression of trade, or to both, it would be difficult to say. But the fact remains that the lowest sum raised by this means since 1874 was £6029 in 1887, which gradually improved to £6973 in 1891. Last year there was again a falling off and great efforts have been made to prevent its repetition this year. The weather was most inclement, but while some of the collections show a decrease, an almost equal number show an increase over the sum collected last year. The mayor, Mr. R. D. Holt, attended in state the Renshaw street Unitarian Chapel, of which congregation he has been a member for many years past. After an eloquent sermon by the Rev. J. P. Jacks a collection was made which amounted to the magnificent sum of £709 9s. 8d. Many other handsome collections are announced, but it would be premature to attempt any estimate of the total at present.

Action against a Cafe Company

In October last a case was before the Court of Passage in which the plaintiff, an inspector of agents in a life insurance company, sued the representatives of the Clerks' Café Company for compensation for illness alleged to be caused by the defendants supplying him with bad food at the Economic Café. The jury disagreed in consequence of which the case was again heard on the 5th and 6th inst. The plaintiff partook of curried steak and stewed rhubarb on June 27th, 1892. He was immediately seized with violent vomiting and diarrhoea and felt stoned in his head. From this date till Sept. 5th no solid food would stay on his stomach. During all this time he was under medical treatment and lost about three stones in weight. On his behalf medical evidence was given to the

effect that the symptoms might be due to putrid meat. For the defence it was contended that none but wholesome meat was supplied to the defendants' cafés, of which they had eight. Medical evidence given for the defendants was to the effect that the symptoms occurred too rapidly to be the result of eating putrid meat. The jury returned a verdict for the defendants.

Small-pox and Revaccination

Although small pox prevails both in Manchester and Warrington, between both of which towns and Liverpool there is constant communication the disease has not made any advance here, any cases that may occur being promptly removed to hospital. The prosecution of the two women (noticed in a previous letter) for concealing the disease has had a very wholesome effect in not only deterring others from doing the same, but in showing all the advantage of working with, not against, the sanitary officers. The select committee who regulate the affairs of the parish of Liverpool afford every facility to those who desire to be revaccinated.

Insanitary Property in Liverpool

On the 7th inst. Mr. Walton, Q.C. M.P., the arbitrator appointed by the Local Government Board to consider the claims for compensation made in regard to property which had been declared to be insanitary, concluded his inquiry. As a proof of the propriety of "presenting" the property in question, it may be mentioned that one man claimed in respect of twelve houses in two courts of two streets. The property was freehold and comprised 575 square yards. It was alleged to be insanitary because of the absence of water-closet accommodation, but the claimant contended that this difficulty could be got over by means of structural alterations. The gross rental was given as £95 and the net rental as £46, but the claimant declined to produce his rent-book. Dr. Taylor, medical officer of health for Liverpool, Dr. Hope, assistant medical officer of health, and Dr. Littlejohn of Edinburgh had all condemned the houses as insanitary and as incapable of being made sanitary. The arbitrator's award will be forwarded to the town clerk.

Taking the Oath with Uplifted Hand

A copy of the resolutions passed at the last ordinary meeting of the Liverpool Medical Institution is published in each of the three local daily papers. One of them, the *Liverpool Mercury*, warmly encourages the new mode of oath-taking, and suggests that all similar organisations of the faculty should follow the example set by the Liverpool Medical Institution. At the trial in the Court of Passage mentioned above the first medical witness, Dr. Smart, declined the book and claimed to be sworn with uplifted hand, which was at once done. His example was followed by all the other medical witnesses, Drs. Nisbet and Hushy, Professor Paul, Drs. Mann and Taylor, and Mr. Vacher. These gentlemen deserve great credit for giving such prompt effect to the resolutions alluded to, and it is now to be hoped that the practice of kissing the book will rapidly become a thing of the past.

January 11th.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Small-pox in the Northern Counties

THE introduction of small pox by tramps and casuals is giving our authorities much concern. Cases have occurred and have spread in this way at Sunderland and Newcastle workhouses. In Durham city, too, cases have been reported and, indeed, all over the county of Durham the disease has got a footing.

Lecture on Pedigrees by Professor Milnes Marshall

Dr. Milnes Marshall, Professor of Zoology in Owens College, Manchester, delivered an admirable lecture in Newcastle this week on Pedigrees. He illustrated some of his theses by familiar animals, such as the horse, which he said is descended from a prehistoric animal with five fingers or toes on each leg now represented by the hoof, but the splints, he said, were the representatives of the four other toes which had disappeared, but were still shown in fossil equine animals.

The Bones Museum at Barnard Castle

I am sorry to say that at a meeting of the trustees and executors of the will of Benoit Josephine Bowes, Countess of Montalto held lately they decided to close the splendid museum and park at Barnard Castle to the public, except

under certain limitations and by ticket. These restrictions have become necessary by the action of the Charity Commissioners refusing an adequate amount to support the museum, and pending the winding up of the estate of the late Mr John Bowes, who was the husband of the Countess of Montalto, the donor of the museum, this is to be the more regretted as there is stated to be sufficient from the estate when wound up to carry out the full intentions of the benefactors.

Carlisle

Last week the usual ball in aid of the Cumberland Infirmary was held in the County Hall, Carlisle. It is two years since the last infirmary ball was held, as the one arranged for last year had to be abandoned owing to the death of Bishop Goodwin. However, last week's festivity seems to have been a great success, as over 250 tickets were taken and it was attended by most of the county families. At the last meeting of the Carlisle Sanitary Authority a letter was read from Dr Lediard pointing out the prevalence of diphtheria and its connexion with what Dr Lediard describes as the filthiest spot in their city, which, he further says, is in the very centre of Carlisle, and he thinks that there is probably not a single member of the Health Committee who was aware that such a dangerous state of matters existed.

Shocking Accident from an Explosion.

On Friday last a shocking accident happened from an explosion at Stanhope, county Durham. A man was carrying a pound of nitro gelatine from the town of Stanhope to the quarry where he worked when it exploded, blowing off both his hands and otherwise injuring him. He was attended by Dr Livingstone, but died the next day.

Death from Chromo Lead Poisoning

A death is reported as having taken place at Jarrow from lead poisoning in a workman aged forty who had been employed as a separator for the past sixteen years. The medical evidence at the inquest was clear as to the cause of death. I have frequently recorded fatalities from lead in the cases of female workers, but very rarely in workmen.

Newcastle-on Tyne, Jan. 11th.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

The Prevention of Waste of Water in Edinburgh

A DRAFT REPORT by the engineers of the Edinburgh Water Trust was submitted to a meeting of the Trust held on Monday. Three districts have been placed under fixed Deacon meters, twelve under Siemens's meters, and twenty six have been laid out and provided with travelling Deacon meters. In connexion with the travelling Deacon meters during the month of November the inspectors sounded 2488 stopcocks, of which number 578 allowed the water to pass during the night. Examining the house fittings supplied by these stopcocks there were found 15 leaden service pipes which had burst, 368 wasting ballcocks, 230 wasting water closets and 130 wasting taps. With regard to the pressure-relieving tanks which had been introduced, the consumption of water had perceptibly decreased during the time they had been in operation. The general conclusion arrived at is that faulty ballcocks are the chief cause of the waste, and that until these are replaced by others of a stronger pattern it will not be possible to effect any material reduction in the consumption of water. To carry out the suggestions of the engineers it is proposed that fifty fixed Deacon meters be ordered. It is mentioned that between 1887 and 1892 the consumption per head decreased from 44 gallons to 39½ gallons. During the last few months, as the result of more rigid inspection of waste and the introduction of pressure-relieving tanks the consumption has fallen to 37 gallons per head—that is, 5 gallons less than in 1889, when night inspection was commenced.

Edinburgh Royal Infirmary

Surgeon General Lithgow has entered upon his duties as Superintendent of the Edinburgh Royal Infirmary, in succession to the late Mr Fyson.

Cookery Demonstrations to Medical Students

As has been the practice for some years past a course of demonstrations of sick room cookery is being given to medical students in one of the theatres of the Edinburgh Royal Infirmary. The course commenced on Saturday last.

Health of Edinburgh.

The mortality last week was 142, making the death rate 23 per 1000. Diseases of the chest accounted for 75 deaths and zymotic diseases for 29, of which 1 was due to typhoid fever, 4 to scarlet fever, 23 to measles and 1 to whooping-cough. The intimations for the week were Typhoid fever 4, diphtheria 3, scarlet fever 56 and measles 263.

The Leith Local Authority and a Local Practitioner

A correspondence has passed between the Public Health Committee of the Leith Town Council and one of the practitioners in the burgh regarding a case of measles said to have occurred in a milk-shop. He was asked if he had told the keeper of the shop that there was no necessity for shutting the shop. The doctor has absolutely declined to be drawn on the subject, reminding them that he is not compelled to report infectious diseases and that he could not recognise instructions from the committee as he is not an official or subordinate of the committee, and that he did not discuss matters concerning his patients with any public or private body. The local authority are getting driven into a corner, and the sooner they yield to the inevitable the better. The action of the medical man in declining to give information is a logical sequence to the action of the local authority and is supported by the law and custom of the profession.

Health of Leith.

There were 40 deaths in Leith last week, making the mortality 29.70 per 1000, which is a considerable fall compared with the preceding weeks. Of the deaths, 2 were from scarlet fever, 1 from diphtheria, 5 from measles and 1 from whooping-cough.

Health of Aberdeen

The following is the return of zymotic diseases notified last week—Measles, 51, scarlet fever, 9, diphtheria, 2, whooping-cough, 3, puerperal fever, 1 total cases, 67. The epidemic of measles continues rapidly to decline, the number of cases for the last five weeks being 263, 184, 147, 106 and 51 respectively. In October, November and December, 1892, the total number of cases of measles was 4358, with 98 deaths in the first two months.

Aberdeen Hospital Sunday

On Jan. 1st the offertories of many churches were devoted to the maintenance of the Aberdeen Royal Infirmary. Despite the inclement weather a good sum was collected—£725, being £24 less than last year. It is hoped that the deficiency will yet be made good.

January 10th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Poor law Relief

FROM a return recently issued by the Local Government Board it appears that the total number of persons who received relief in 1892 amounted to 427,934, showing a decrease of 9954 as compared with 1891. Of these 308,435 received in-door relief and 119,499 out-door relief. The total expenditure under all heads was £1,402,919, compared with £1,405,305 in the previous year.

Cholera Hospital, Cork

The Cork guardians have adopted the plans sent by the Local Government Board for a cholera hospital in the grounds of the workhouse. The hospital will accommodate thirty patients and will be commenced as soon as plans and specifications have been prepared.

Fees to Sanitary Officers

In December last the board of guardians of the Cork Union adopted a motion proposing to discontinue the practice of paying special fees to sanitary medical officers for attendance at petty sessions in respect of sanitary matters. This proposal was not only unjust but manifestly illegal, and the Local Government Board, on being appealed to, pointed out that Section 258 of the Public Health Act, 1878, enables a sanitary authority to arrange with a candidate for the office of medical officer before appointment that the duty of attendance and affording assistance at sanitary prosecutions shall be included in his salary, but that under other circumstances there is no power to enforce the arrangement contemplated in their notice of motion.

Rathdown Union.

The guardians of this union have elected Dr O'Flaherty

d Mr Newland superintendent medical officers under the olera regulations for this union.

Children's Hospital, Dublin.

A new juvenile comedy operetta will be performed at the eatre attached to the hospital in Harcourt-street in aid of the funds of the institution on the 21st inst. The play will be "Cinderella" and the chorus will include thirty children.

Sir Charles Cameron of Dublin has been elected President of the Public Analysts' Society of Great Britain and Ireland. Dr Thomas Myles has been appointed by the Treasury Medical Referee for Ireland in connexion with the Civil Service id superannuations.

The Belfast Health Society

The new Health Society was very successfully inaugurated on Jan 4th, when at a public meeting Dr Whittaker medical officer of health for the city of Belfast, delivered a lecture on "Sanitary Science." The President of Queen's College, Dr. Hamilton, who as President of the Health Society occupied the chair, pointed out that Mulhall's statistics for 1861-80 showed that Ireland was the healthiest country in Europe. In Hungary the death rate is 38 per 1000 per annum, in Austria 30 Italy and Spain 29 Belgium 22, England 21, Scotland 21, Denmark and Sweden 19, Ireland 17. But while this fact is true in regard to Ireland as a whole, unfortunately the large towns of Ireland, Belfast amongst the number, are among the unhealthiest in the United Kingdom. In Birmingham the death rate is 19 per 1000, in London 21, in Glasgow 25, in Liverpool and Cork 28, in Dublin 27 and in Belfast (the worst of all) 23. In his lecture Dr Whittaker showed the great prevalence of phthisis in Belfast (1017 died from this cause in 1891 and 1032 in 1892) and he said that the preventable causes of disease existing in this city were—1) the unhealthy occupation of many of the working classes, 2) the presence in the backyards of thousands of the houses of the working classes of middens of the worst possible type, (3) the bad sanitary conditions in far too many of the workers' houses, and (4) the imperfect drainage of the houses into the sewers. A very important statement was made by one of the speakers at the meeting—Mr Thomas Harrison, a member of the Public Health Committee of the Belfast Corporation. He said all the efforts of that Society would be of little avail unless they and the public could get the Infectious Diseases Notification Act introduced into Belfast at the very earliest opportunity. At present Dr Whittaker (the public officer of health) and his large and efficient staff know nothing of the march of disease through their town. They must not, Mr Harrison said, blame either the Public Health Committee or the Legislature, the Belfast Corporation refused to pass a resolution in favour of the adoption of the Act. Even so late as Monday, Jan. 2nd 1893, another attempt to get the Act introduced was unsuccessful. He called upon the Medical Society of Belfast and upon the newly organised and newly established Health Society to assist the Public Health Committee, even against the corporation itself, to get that Act introduced into Belfast. There is no doubt that this new society (the inception of which is entirely due to the ceaseless energies of the hon. secretary Dr H. O'Neill) will do an immense deal of good especially in educating the citizens as to the laws of health, and already by the attention it has drawn to the very high death rate of Belfast, it has accomplished no small end.

Jan. 10th.

PARIS

(FROM OUR OWN CORRESPONDENT.)

Revival of an Ancient Remedy for Phylloxera

On April 11th last M de Mély called the attention of the members of the Académie des Sciences to book vii., chap. viii. of Strabo's Geography, wherein mention is made of an insect or parasite—perhaps our own phylloxera—which already at that remote period, 60 B.C. attacked the vine. Roughly translated the passage runs as follows—"The Apollonates have in their territory a rock which vomits fire, from its base there escape springs of tepid water and asphalt, the result, apparently, of the combustion of the soil, which is bituminous as is proved by the presence on a hillock close by of an asphalt mine. In this mine the loss seems to be balanced by fresh deposits derived from the soil thrown in, which is converted, according to Posidonius,

into bitumen. The same author mentions another bituminous earth, ampelitis, which is extracted from a mine in the neighbourhood of Seleucia and which is employed as a preservative against the insect that attacks the vine. The mere rubbing of the vine with a mixture of the earth and oil suffices to kill the animal before it can ascend from the roots to the buds. Posidonius adds that when he was Prytanis of Rhodes there was found there a similar earth, which, however, required more oil than the above (ampelitis)." M. de Mély has since conducted experiments on a large scale in order to put Strabo's assertion to the proof. Six hundred vine stocks, planted on land impossible to sulphur, were treated with 100 kilogrammes of chopped rags saturated with ten kilogrammes of schist. M. de Mély has in addition treated some vines with bituminous earth sent him from Rhodes, the earth being placed in circular buckets around the vine stock. The result is said to be most gratifying, the vines subjected to the Strabonian treatment being remarkably vigorous and the yield of grapes greatly superior to that of neighbouring vines untreated thus. M. de Mély suggests that the method should be put into practice throughout all phylloxera infested districts, the moderate cost of the remedy bringing it within the reach of even the poorest wine-grower.

Remarkable Transposition of Organs

Some days ago there died in Paris, under what appeared to be suspicious circumstances a gentleman of independent means aged eighty-five. A necropsy was deemed necessary, and Dr Descouts the well known Morgue expert, was entrusted with the task. No abnormal cause of death was discovered, but Mohère's famous *Médecin malgré lui* could he have been present on the occasion, would have been gratified to find his peculiar topographical notions confirmed in a striking manner. The heart, liver and spleen were completely transposed, the first named organ being on the right side of the chest and so on. Commenting on this strange abnormality Dr Descouts remarks on its rarity. He further says that he would like to know how many errors of diagnosis have been committed by the different practitioners who were consulted by the defunct during his long life. Asked if it would not be as well to interrogate the deceased's ordinary medical attendant, Dr Descouts humorously replied that it was most unlikely that he had ever had one and that that was probably the reason he had lived so long! Dr Descouts has evidently studied Mohère to some purpose.

The new Medico legal Institute

Anyone who, like myself, has followed a series of summer lectures at the Morgue will not readily forget the suffering entailed on the students by the sweltering heat prevailing in the wretched little theatre in which post mortem examinations are performed by a volunteer from amongst the audience. The teaching is so excellent that both Professor Brouardel and his assistants and the Faculty students deserve to be provided at an early date with more appropriate premises. The construction of a new Medico-legal Institute has for some time past been on the tapis and it is now announced that the discussion of the project will be definitely undertaken by the Conseil Général du Département de la Seine in February next. Fortunately for the chances of the prompt realisation of the scheme Professor Brouardel possesses great influence, which he will doubtless employ in this direction.

January 11th.

BERLIN

(FROM OUR OWN CORRESPONDENT.)

The Emperor and Empress Frederick Children's Hospital

THE Emperor and Empress Frederick Children's Hospital in the Reinkendorfer Strasse here, of which the Empress Frederick is patroness, is an institution for the treatment of sick children, especially such as are suffering from infectious diseases. It was founded and is maintained mainly by beneficent donations. The hospital consists of four departments—one for non-infectious internal diseases another for surgical cases, a third for diphtheria and a fourth for scarlet fever. The doctors and attendants are as strictly isolated in the several departments as if they did not belong to a uniformly governed institution. Other departments for measles whooping cough and mixed forms of infectious diseases are projected. The institution was opened on Aug 1st, 1890 and then consisted only of the consulting and diphtheria departments. During the first year 494

children were treated in the hospital, including 242 suffering from diphtheria, 36 from scarlet fever and 216 from non-infectious diseases or injuries, and the total number of days spent by them in the hospital was 11,127. The number of children treated in the consulting department was 5674. Since then till the end of 1892 the corresponding numbers were 1752, 46,460 and 8000. The sum still wanted to complete the hospital is about 300,000 marks (£15,000).

Friedrich von Esmarch

Yesterday was the seventieth birthday of the famous surgeon Professor von Esmarch. He received numerous marks of sympathy and respect. Prince and Princess Henry of Prussia and all the leading people in society at Kiel, where he lives, were amongst his congratulators. Professor Petersen delivered a festal document in the name of his pupils and admirers. The city of Kiel sent a deputation with the burgomaster at its head. The congratulations of the University were conveyed by Professor Haeckel. The students' associations were represented by deputations. Many telegrams &c. arrived from abroad, especially from America.

Professor Eichstedt

The death of Professor Eichstedt, the oldest member of the medical faculty of the University of Greifswald in Pomerania, is announced from there. He was a many-sided medical writer. Some of the subjects on which he wrote were diarrhoea in children, procreation and the mechanism of labour, acarus scabiei, and pityriasis versicolor. He was born and educated at Greifswald, and spent most of his life there.

Dr Leon Hollstein

Privy Sanitary Counsellor Dr Leon Hollstein died two or three days ago aged eighty-one. He spent sixty years of his life in Berlin. He was the author of a "Manual of Anatomy" which was the first, or one of the first, German books of the kind which followed the English example of inserting illustrations in the text. It went through five editions, was translated into foreign languages and was very popular amongst medical students till about twenty years ago.

Cholera in Hamburg

About six cases of cholera occurred in Hamburg last week.

Professor Hitzig

Eduard Hitzig, Professor of the Science of the Treatment of the Insane at Halle, has received and declined a call to succeed Professor Theodor Meynert in Vienna. January 10th.

VIENNA

(FROM OUR OWN CORRESPONDENT.)

Cholera in Austria Hungary

No case of cholera has been reported from the Galician towns, but a new invasion of the epidemic is feared in the Bukovina on account of the rapid spread of the disease in the adjacent part of Russia. The traffic on the frontier is, therefore, kept under medical supervision. A case of cholera has occurred at Budapest to-day, but the number of the patients at the Cholera Hospital has been reduced to two.

The Intra-peritoneal Insufflation of Air in Tuberculous Peritonitis

The astonishing curative effect of simple laparotomy is well known from the publications of Professor Oheyne as also from those of Continental surgeons, and various hypotheses have been advanced to explain it. Now Professor Mosetig Moorhof, in a recent communication, is inclined to believe that the curative influence of laparotomy in tuberculous peritonitis is due, as was originally suggested by Caspersohn, to the irritation caused by the entrance of air into the peritoneal cavity. His attention was called to this fact in a case of tuberculous growths of the peritoneum in a woman aged forty-two, on whom laparotomy had been performed merely for the purpose of diagnosis, and in whom three weeks after the incision of the abdominal wall the growth was reduced from the size of a child's head to that of an apple without any further interference. In May, 1892, Professor Mosetig had the opportunity of trying a new method of treatment based on this experience. In a boy four years of age, with ascites hydrocele of the cord and tuberculous induration of the epididymis and of the vas efferens, the tuberculous testicle was removed, and by introducing a

drainage tube through the tunica vaginalis and the inguinal canal the ascites was drained off, 1700 cc. of liquid containing albumen being discharged. Then air, sterilised by passing it through a solution of warm carbolic acid and again through layers of cotton wool which dried it, was insufflated into the peritoneal cavity through the drainage tube. The ascites disappeared, the boy quickly recovered, and in October the abdomen was, on percussion, found to be normal when the patient was again seen by the surgeon. From these facts Professor Mosetig was induced to recommend paracentesis abdominis with subsequent insufflation of air in cases of tuberculous peritonitis associated with ascites, in place of the laparotomy heretofore performed in such cases.

The Value of Different Antiseptics in the Surgery of the Brain

By recent experiments of Professor Adamkiewicz it would appear that some of the antiseptics used in surgery should not be applied to wounds of the brain, as they are irritating to or even destructive of, the nervous tissues. Carbolic acid, for example, should not be used in stronger solutions than 0.5 per cent., while corrosive sublimate should be altogether avoided. Boric acid alone is freely applicable to the brain without evil consequences.

Forensic Medicine in Vienna

There were not less than 1108 post-mortem examinations made in Vienna at the Institute for Forensic Medicine in the course of last year, a number greatly in excess of the necropsies performed at other universities.

Vienna, Jan. 2nd.

Obituary.

ROWLAND SMITH M.R.C.S., L.S.A.

ONE of the rank and file of our profession passed away somewhat suddenly at Cobham, Surrey, on Monday, Jan. 2nd. Mr Smith belonged to the class of general practitioners, whose services to the sick and ailing of the community are for the most part confined to the sick. For between thirty and forty years he held offices at the above-mentioned town under the Poor law, his ministrations in the course of his official duties being concurrently sought also by his neighbours in the easier walks of life. The severe weather with which we have been visited of late, together with the exposure necessarily attendant on his professional duties, seems to have brought on an attack of pneumonia to which he speedily succumbed. The esteem in which he was held by his neighbours as well as by his patients was shown by the deceased being honoured by a public funeral. He leaves six sons and two daughters to mourn their loss.

JAMES ALLEN BRATTON, M.A. CANTAB., L.R.C.P. LOND., M.R.C.S. ENG.

MR. J. A. BRATTON died at Ewell, near Epsom, on Monday the 9th inst., of enteric fever, after an illness of five weeks' duration. During the night of Sunday symptoms of pneumonia involving the whole of the right lung supervened, and he rapidly sank. He was the son of the late Mr James Bratton, F.R.C.S., a well-known surgeon, who practised for nearly fifty years in Shrewsbury. Mr J. A. Bratton was educated at Caius College, Cambridge, and at King's College, London, and at first practised in Shrewsbury, where he became assistant surgeon to the Shropshire Eye, Ear and Throat Hospital and honorary secretary and treasurer to the local branch of the British Medical Association. In 1890, wishing to be nearer London, he joined Dr Barnes of Ewell in partnership, and on the death of his partner last year he took over the whole of the practice. He was a thorough, able practitioner, most courteous and agreeable in manner, kind and genial in disposition, and he readily won and retained the confidence and esteem of his patients. He died at an early age of thirty-two and his loss will be severely felt by a large circle of patients and friends. He leaves a widow and one child to mourn his death. His body was cremated at the Woking Crematorium on Thursday, the 12th inst., according to his expressed desire.

DR RAFFAELE D'ARPE

THE picturesque and historically most interesting Apulian town of Lecce has just lost its noblest citizen, the nonagenarian Dr Raffaele D'Arpe. Seventy years ago he was

of the most promising graduates of the Neapolitan school, he had barely entered in practice when the patriotic ferment in the peninsula absorbed his time and energies. Uprisings of 1821 and 1831 found him actively aiding the national cause and, after their subsidence, utilising much of his leisure in preparing for the next and, temporarily, more active one in 1848. By this time long years of steady practice and study had made him one of the most successful consultants in Italia Meridionale, in which capacity he was especially useful to the patriots confined after that memorable uprising in the prisons of Lecce. Among these were some of the most noted martyrs of the South—the Duca di Stromeo, the Senator Schiavoni, the Signori Stancchia, Sansovito, Bortone and others—all of whom owed to his courageous and kindly visits not only the treatment which prolonged their lives but the mental satisfaction of knowing how their brethren were faring at other centres of the national movement. At last the Neapolitan Government ventured to put him also under arrest and he served some time in the dungeons of Lecce till the temporary return of peace set him at liberty. Once more the agitation against the Bourbon in 1859 found him on the nationalist side. With the absorption of the Two Sicilies into the Italian kingdom in 1860 Dr D'Arpe became Mayor (*Sindaco*) of Lecce and held the post with much acceptance for many years. Though in exceptionally good circumstances, he laboured professionally to the last, principally among the poor. By these, and indeed by all the inhabitants of the town and province, his death is mourned as a public calamity. On the day of his funeral—a most touchingly impressive one—the schools, the shops, the places of business were closed in order that the citizens of every class and condition might pay their last tribute of respect to one who had served them so unweariedly and so well.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY MEETING of the Council of the Royal College of Surgeons was held on the 12th of January, the President, Mr Thomas Bryant in the chair.

With the exception of a resolution relating to a candidate for the dental diploma the minutes of the Ordinary Council on the 8th ult. were read and confirmed.

The Secretary reported the death, on the 18th ult., of Mr Richard Owen, K.C.B., F.R.S., Senior Fellow of the College and late Conservator of the Museum of the College, and the Council expressed their deep regret at his death and their sincere sympathy with the members of his family.

It was agreed that, as recommended by the Museum Committee, Mr E. Burgess, the museum artist, should be employed for a further period of six months, that Dr T Colcott Fox and Dr H. Radcliffe Crocker should be requested to rearrange the models and drawings in possession of the College and to prepare a new catalogue, and that, as recommended by the Museum Committee, the sum of £15 should be expended in the purchase of 108 Brazilian birds preserved in spirit. A report, dated Dec. 19th, 1892, from the Committee of Management was approved, adopted and entered on the minutes, a report, dated Dec. 9th 1892, from the Laboratories Committee, was also approved, adopted and entered on the minutes. Dr German Sims Woodhead was re-elected Director of the Laboratories for the ensuing year.

It was agreed that as recommended by the President and Vice Presidents, the Royal Horticultural Society should be informed, in reply to their letter of the 30th ult., that the President and Vice-Presidents will be prepared to sign, on behalf of the Council, any memorial that may be presented by them to the London County Council asking them to undertake an inquiry into the origin and composition of London fogs and the possibility of a remedy for the same.

The Secretary reported the receipt of a dissertation on "Diseases of the Ovaries and the Uterine Appendages their Pathology, Diagnosis and Treatment," the subject of the Jacksonian Prize for the past year.

The motion brought forward by Mr Smith was agreed to, it was as follows—

"That in order to ascertain the views of the Fellows and Members of the College on the position which in their opinion this College should hold in the proposed Teaching University for London separate meetings of Fellows and Members be convened at an early date after the report of the Gresham Royal Commission has been made public."

Mr Tweedy obtained the permission of the Council to withdraw the motion, of which he had given notice on the 8th ult.

A communication was received from Sir Francis Knollys announcing the intention of his Royal Highness the Prince of Wales to honour the College with his presence at the Hunterian Oration on Feb 14th next. The oration will be delivered in the theatre of the College by Mr Thomas Bryant.

MEDICAL TRIAL

MEDICAL PRACTITIONERS' ACCOUNTS

A CASE was recently tried at the Greenwich County Court, before Judge Bristowe, Q.C., and a jury, in which the plaintiff, Dr Groome of New Cross, sued the son of a patient, formerly living at Streatham, for the recovery of £50 for medical attendance on the deceased. From the evidence it appeared that in November, 1890, the defendant's sister called at the plaintiff's surgery and produced a letter from the defendant to her by which she was asked to procure for her father such medical attendance as he required. Upon the faith of this letter the plaintiff attended the patient for a period of thirteen months, when he died. Shortly after the death the plaintiff sent in his account, made out to the executors of the deceased, which account was sent by the defendant's sister to him, and some correspondence took place between the plaintiff and the defendant with regard to the payment of the claim. The defendant did not deny his liability, but, on the other hand, there was no express admission of it. Whilst this controversy was taking place the defendant's sister died, and thus a further complication was introduced into the matter. At last the plaintiff, being unable to obtain payment, commenced this action. The vital point in the case was to establish the defendant's liability, and the proof of this was dependent on a letter of the deceased to the sister, which letter however, was not forthcoming. After evidence to sustain the points brought forward on either side had been given the judge, in summing up, commented on the negligence displayed by medical practitioners generally in regard to the delivery of their accounts for professional attendance, and the jury found a verdict for the plaintiff for the full amount, with costs.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in Anatomy and Physiology at a meeting of the Examiners on the 9th inst.—

George A. Copland, William Butement and William L. Christie students of Otago University, New Zealand, and London Hospital. William H. G. Aspland, London Hospital. Harry G. Cribb and Arthur S. Lawrence of Middlesex Hospital. John W. Maskell, of University College Liverpool. Ernest J. Beards, of Mason's College, Birmingham. Thomas E. Price of Mason's College, Birmingham and Mr Cooke's School of Anatomy and Physiology. Joseph Gallizia, of the University of Malta. Naoroji Baramji Darabseth, of Grant Medical College, Bombay and Aberdeen University. John M. K. Grover, of Owens College, Manchester. James H. Ferguson, of Ledwith Medical School and the Catholic University, Dublin. Thomas G. D. Cooper of Queen's College, Cork, and Wilfred F. Evans, of St. Bartholomew's Hospital. Anatomy only—Herbert Hallam, Ernest D. Watren, and Cyril H. Flory of the Medical School, Sheffield. Stanley W. Williams and Arthur T. Jones of University College Liverpool. Charles H. Smart, of Mason's College Birmingham. Thomas Jones and Edward Melden, of Owens College, Manchester. Alfred E. Sears, of London Hospital and Henry A. Burridge of King's College. Physiology only—Arthur E. Little and Arthur T. Latchmore, of Yorkshire College, Leeds. Ernest H. Millon of St. Mary's Hospital. Richard E. W. Jennings, of the Medical School, Bristol and Mr Cooke's School of Anatomy and Physiology. Thomas T. Harmit, of Middlesex Hospital. Edwin Follitt, of St. Bartholomew's Hospital. William Chapman and William H. Tomlinson, of Owens College, Manchester. Arthur Cant and William Sutcliffe of Mason's College Birmingham.—4 candidates were referred in both subjects 6 in Anatomy only and 12 in Physiology only.

Passed on the 10th inst.—

Anatomy and Physiology—Arthur Marriott, Thomas H. C. Stevenson and John H. Cook, of University College. George H. Hunt, of St. Mary's Hospital. Thomas H. Boyd, of Melbourne University. Frederick D. S. Fayer of Cambridge University and Charing Cross Hospital. Arthur H. H. Huckle. Walter C. Pakes of Guy's Hospital. Charles D. Statham, of Grant Medical College, Bombay, and Guy's Hospital. Ernest W. H. Groves and Frank A. Smith, of St. Bartholomew's Hospital. William H. Kendrick, of London

Hospital, Arthur J Eastcott and Edward L. Hunt of St George's Hospital, Herbert C Crouch of St. Thomas's Hospital, Reginald Moreton, of St. Thomas's Hospital and Mr Cooke's School of Anatomy and Physiology Usher W. N. Miles, of King's College, Hugh P. Noble, of Middlesex Hospital
Anatomy only—John P. Prell, of London Hospital
Physiology only—Denyer W. F. Latham and Charles F. Le Sage, of London Hospital Herbert J. Richard and Bernard W. Holmes of St. Bartholomew's Hospital Oguntola Sapara of St. Thomas's Hospital, William D. Watson and Edgar T. Inkson of University College and Christopher A. A. Coulthard of St. George's Hospital.—12. Candidates were referred in both subjects, 5 in Anatomy only and 4 in Physiology

Passed on the 11th inst. —

Anatomy and Physiology—Hubert Rawsthorne of University College, Reginald A. L. Hill and Percy S. Crookes, of St. Thomas's Hospital, Arthur Chopping of St. Thomas's Hospital and Mr Cooke's School of Anatomy and Physiology Julius Moore and Lionel A. Paul, of Guy's Hospital Leonard A. Grimes, of St. George's Hospital and Mr Cooke's School of Anatomy and Physiology Spencer Wicks of Cambridge University and London Hospital, Frederick L. Dodd, of Middlesex Hospital James M. G. Swainson of Westminster Hospital, John Gundlach, of St. Bartholomew's Hospital.

Anatomy only—Frank V. Bice, William A. Bramsdon, Herbert G. Berry and Thomas Martin of St. Bartholomew's Hospital, Arthur W. Robertson, of St. Bartholomew's Hospital, and Mr Cooke's School of Anatomy and Physiology James G. Heath, of St. Mary's Hospital Frederick R. Baker, of London Hospital, and Mr Cooke's School of Anatomy and Physiology, Ralph E. De Martini, of King's College.

Physiology only—Harry R. Emms Arthur Brebner and Frederick H. E. Anning of University College, Lambert C. Dillon, of King's College Michael Joseph Evan and William H. Farmer, of St. Bartholomew's Hospital, William K. Hay Coghlan of St. Mary's Hospital and Harold E. Dixon of London Hospital.—12 candidates were referred in both subjects, 5 in Anatomy only and 8 in Physiology only

ROYAL COLLEGE OF SURGEONS OF ENGLAND—

The following gentleman, having previously passed the necessary examinations and having conformed to the by laws and regulations, was, at the quarterly meeting of the Council, admitted a Member of the College —

Samuel Whitell Thompson, L.S.A. Lond., Charing-cross Hospital.

SOCIETY OF APOTHECARIES OF LONDON—The following candidates have passed the Primary Examination in the subjects indicated —

Chemistry—C. Adams, M. K. H. Holt, H. M. Maitland W. H. Burnhill, and M. Sharp, Royal Free Hospital T. H. P. Peers, Charing-cross Hospital

Materia Medica, Botany and Pharmacy—W. MacLellan Edinburgh, J. Thornton, London Hospital.

Anatomy and Physiology—F. H. Blatchford Cambridge and St. Mary's Hospital H. G. Gibb Middlesex Hospital H. C. F. Dalton, Charing-cross Hospital L. C. Dillon, King's College A. M. Dow Yorkshire College, Leeds A. S. Lawrence, Middlesex Hospital C. R. Maitland, Cambridge University, C. H. R. Pentreath Cambridge and St. Mary's Hospital T. E. Price, Birmingham and Mr Cooke's School of Anatomy, W. S. Robinson, Birmingham O. C. Sibley Middlesex Hospital

Anatomy—W. Alder Guy's Hospital, L. M. Blake, Royal Free Hospital D. L. E. Boctor, St. Bartholomew's Hospital, G. H. Gill Owens College S. R. Hallam St. Thomas's Hospital H. G. Jones and E. S. Johnson St. Mary's Hospital E. S. I. Lovell Charing-cross Hospital A. C. M. Levan King's College E. D. Warren University College and Sheffield

Physiology—E. H. Betts St. Bartholomew's Hospital, A. T. Latchmore, Yorkshire College Leeds W. A. Montgomery, St. Thomas's Hospital, A. P. Square Middlesex Hospital, M. A. F. Vakil, Royal Free Hospital and Bombay

ISOLATION OF INFECTIOUS CASES AT CHEADLE—

The Cheadle Local Board have obtained the consent of the Stockport Corporation to send infectious patients to the Stockport Borough Hospital if accommodation can be found for them at that institution. The nearest place of isolation, independent of the Stockport Borough Hospital, is Hyde, which place, it is contended, is too far distant from Cheadle. Efforts have been made to erect an infectious disease hospital at Cheadle, but to that proposal the majority of the Board and of the ratepayers are opposed.

HARVEIAN SOCIETY—The annual meeting and conversazione will be held at the rooms of this Society in Tichborne street, London, on Thursday, Jan. 19th, at 8 P.M., when an address will be given by the retiring President, Dr. Cheadle. Amongst the names of those gentlemen who have promised to exhibit pictures are Sir Henry Thompson, Mr. (Propert), Dr. Buzard and Mr. Evershed. The following officers have been nominated by the Council for 1893—President Mr. Malcolm Morris Vice-Presidents Mr. Drew Dr. Goodhart, Mr. Lockwood and Dr. Maguire. Treasurer Mr. Cripps Lawrence. Hon. Secs. Mr. Roughton and Dr. Boxall Council Dr. Cheadle (retiring President), Dr. William Hill (retiring Secretary), Dr. Coates, Mr. Dodsworth, Dr. Evans, Dr. Gomer Davies, Mr. Rayley Owen, Mr. D'Arcy Power, Mr. Morton Smale, Sir William Roberts, Dr. Scanes Spicer and Dr. A. K. Willis

MEDICAL FEES AND STREET ACCIDENTS—In Glasgow the Police Commission has fixed the minimum fee for medical attendance on persons suffering from street accidents at 2s. 6d. during the day and 5s. during the night, the maximum payment to remain as heretofore.

FOOTBALL CASUALTIES—On the 2nd inst. during a match at Lochmaben, a player fractured his right leg.—On the following day while playing a match at Gleadless, a young man dislocated his right clavicle.

PRESENTATION—Mr. F. H. Lewis, M.R.C.S. L.S.A., of Auckland, New Zealand, has been presented by the Central Nursing Class of the St. John Ambulance Association with a silver cigarette case and match box in recognition of his services in training the class.

TYPHUS FEVER IN NEW YORK—Stringent measures are being adopted to curb the epidemic now prevailing in New York. Cases to the number of eighty-one have been reported since Dec. 1st, and most of them have arisen in densely populated and grossly insanitary portions of the city. The closing of some of the lodging houses is in contemplation.

STRANGE CASE OF SUICIDE—On Jan. 4th an inquest was held at Birmingham on the body of an elderly man named William Bolas. Deceased had lately attempted to commit suicide by drinking sulphate of zinc. Evidence given before the coroner showed that the unfortunate man had swallowed two pieces of cane, the one fifteen inches in length and the other sixteen inches. Death resulted from injuries to the windpipe and the jury returned a verdict of "Suicide during temporary insanity."

THE SOCIETY FOR THE STUDY OF INEBRIETY—A meeting of the friends of this Society, which assembled at the Marlborough Rooms on the 10th inst., was distinguished by an event of unwonted interest. This was the celebration of the hundredth anniversary of one of its vice presidents, Dr. Severn Wielobyski. Dr. Norman Kerr, surrounded on the platform by many gentlemen identified with the work of restraining intemperance, gave an interesting sketch of the career of the veteran reformer and, on behalf of the Society, presented him with an illuminated address appropriate to the occasion. Other addresses from kindred societies as well as from private persons interested in the work of temperance reform were also presented. Dr. Wielobyski, in expressing his thanks for the addresses and congratulations, remarked that in order to live a hundred years it would be necessary to abstain from alcoholic drinks and the use of tobacco and to forego over-indulgence in animal food.

PROVISION AGAINST FIRE IN HOSPITAL BUILDINGS. Berrywood County Asylum, Northampton, is, in addition to its other fire protective arrangements, to be supplied with a powerful steam fire engine of special design. Messrs. Shand, Mason and Co. of London are the makers of the engine, which is to have a pumping capacity of 450 gallons per minute and will throw six powerful jets of water over the asylum buildings if occasion should arise. A novel feature of the engine is that it can be converted into an ordinary motive power engine at a few minutes' notice.—The Governors of Guy's Hospital recently had large additions made to the fire main and hydrant system which has for many years protected the premises against fire. Messrs. Merryweather and Sons carried out the work and recently gave one of their periodical drills to thirty-two of the night staff and six workmen, with very good results.

THE RECENT INQUIRY AT THE BIRMINGHAM WORKHOUSE INFIRMARY—The clerk to the Birmingham Workhouse Infirmary has received from the Local Government Board their report with regard to the inquiry recently conducted by their inspectors, Mr. Murray Browne and Dr. Downes, into the circumstances connected with the death of Edwin Hawkesford at the Winsor Green Asylum in July last, also in respect of the case of Joseph Aston, a certified lunatic, whilst an inmate of the workhouse infirmary. The report gives in detail the conclusions of their inspectors regarding the circumstances attending the former case, and on the whole, whilst admitting the existence of some error of judgment in dealing with the case, agree with the report of their inspectors that no serious blame is to be attached to the officials concerned. The second case was that of an old man who suffered from a fractured sternum. Here the accident seemed to have arisen from an altercation between the deceased and another patient.

ODONTOLOGICAL SOCIETY—At the annual general meeting of this Society, held on Jan. 9th, the following officers for the present year were duly elected.—President Mr W Bowman MacLeod. Vice-Presidents Messrs T H G Larding, R H Woodhouse, Morton Smale, R T Stack, F H Talkwill, W E Harding. Treasurer Mr S J Hutchinson. Librarian Mr Ashley Gibbings. Curator Mr Storer. Editor of Transactions Mr E Lloyd Williams. Honorary Secretaries Messrs W A Maggs (Council), Cornelius Robbins (Society), James F Colyer (for Foreign Correspondence). Councillors Messrs F J Bennett, E G Betts, B J Bonnell, J Ackery, A Underwood, Harry Rose, J D Davis, Chas Truman, W R Humby, T S Carter, V S Woodburn, W H Williamson, H C Quinby, D W Moore, Wilson Hogue, G G Campion, J McKno Ackland, H. McCall.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET Office directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BEST PALEMON, M.B. Lond. M.R.C.S., has been reappointed Medical Officer for the Grimsby Sanitary District of the Louth Union.

BRANDT J. EGBERTS, B.A. Cantab., M.B. C.M. Edin. has been appointed House Physician to the Hertford British Hospital, Paris.

BROWN HAYDN L.R.C.P. L.R.C.S. Edin., L.F.P.S. Glasg. has been appointed Surgeon to the Hospital of St. Peter Port, Guernsey.

COLLINS, HENRY BEALE, D.P.H. has been appointed Medical Officer of Health for Kingston-on-Thames Urban District.

DAVIES, G. A. L.R.C.P. Lond. M.R.C.S., of Newport (Mon) has been appointed a J.P. for that Borough.

DAY, F. W. LANGSTON M.R.C.S. L.R.C.P. Lond., has been appointed Medical Officer of Health for the Baldock District, Herts.

DUKES, Mr ARCHIBALD has been appointed House Surgeon to the Croydon General Hospital, vice De Mesquita, resigned.

HITCHCOCK, JAS M.B. C.M. has been appointed Medical Officer pro tem to the Gamrie Parochial Board.

LEA, J. M.B., C.M. Cantab., has been appointed House Surgeon to the Stockport Infirmary.

MAGUIRE, R. M.D. F.R.C.P. Lond. has been appointed Physician on the Honorary Staff of the Royal Society of Musicians.

MCNELL, HARDINGE C.C., L.R.C.S. L.R.C.P. L.F.P. & S.G. Edin. has been appointed Honorary Surgeon to the Cornelia Hospital, Poole.

MILLER, W. R. M.D. B.Ch. Dub., has been appointed Surgeon to the Royal Cornwall Infirmary.

ODELL, ROBT L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for the Second and Third Sanitary Districts of the Hertford Union.

OWEN, E. M.B. Lond., F.R.C.S., has been appointed Surgeon on the Honorary Staff of the Royal Society of Musicians.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to an gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to the Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

PUBLISHER'S NOTICE

In order to facilitate the work of reference to the volume of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together.

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET.

REGULATIONS CONCERNING PATENT MEDICINES ON THE CONTINENT.

ACCORDING to an American Consular report which is referred to by pharmaceutical contemporary, the regulations of several European countries concerning patent medicines are a good deal more stringent than those of Great Britain. In Austria Hungary prepared medicines, whether patented or not, unless imported for druggists, require a special permit from the Customs authorities. All medicines as medical compounds are excluded from protection by the Austrian Patent Law, and the sale of such is permitted only to and in drug stores. In Belgium patent medicines can only be sold by apothecaries or other authorised persons, and must bear the seal of the

her who assumes the responsibility of the product. In Denmark a sale is confined to apothecaries. France entirely prohibits the sale of secret medicines unless they are approved by authority and the formula is inserted in the official formulary. In Germany all proprietary medicines must be retailed by a regularly sworn and licensed apothecary who is responsible for their effect on the patient, but the most serious restriction is the prohibition of advertisements of patent medicines in public journals when such medicines are made by a secret formula or process. This law is rigorously enforced in Baden and Prussia but less stringently so in Württemberg, Bavaria and some parts of Northern Germany, while in Saxony the authorities exercise the right of prohibiting the sale altogether. In Italy the composition of a patent medicine must be approved by the Board of Health. No patent medicine is allowed entry into Russia unless special permission is on each occasion obtained from the Medical Department of the Minister of the Interior. If, after careful examination it is proved that the production of such medicines requires elaborate work and expensive apparatus it is allowed entry subject to a duty of about 1s. 8d. per pound. In London provided such medicines are regarded as beneficial and are compositions durably preserved. In Sweden, Switzerland and Turkey there are but few restrictions.

r. Fred W. Woolcock.—1. The medical degrees of Melbourne are registrable in the United Kingdom. 2. The registered holders of them, we should imagine, would be qualified for examination for medical appointments in the army and navy like other registered persons but we are not aware that any such colonial graduates have presented themselves for examination. 3. A gentleman holding diplomas in medicine and surgery from the Melbourne University can practise in both branches in the United Kingdom. In the sense of practising medicine he will be a 'physician, though not so in the restricted sense of practising exclusively as a medical consultant and of being a Member of a College of Physicians. He is of course entitled to call himself a surgeon.

r. F. R. Humphreys.—We know of no society for helping such a case.

'INFECTION AND CONTAGION'

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 31st, 1892, p. 1541 the application of the above terms is discussed and thereby we are given to understand that the word "contagion" is a somewhat convertible term with "contact"—viz. "It would conduce to clearness if the word 'contagion' were restricted to its precise signification of transmission by actual contact." It seems difficult to consider why it is assumed that the words "contagion" and "contact" should have any signification in common, unless indeed that to some there may be a phonetic link between the words. However it is no uncommon error for persons to consider that the substantive "contagion" has some Latin root justifying its applicability of the term so as to imply contact such, however there seems no ground for maintaining, nor, indeed do we find that earlier writers who adopted the word had any such indistinct or confused meaning for it. *Contactus* and *contingens* have no affinity with *contagio* ('an effect'). Further, as regards the use of the word 'To mix contagion to the propagation of disease by contact only would be to disallow the more comprehensive use of the term in our best authors.' (Hancock, "Laws of Pestilence" p. 24.) This author goes very fully into the meaning and use of these terms (chapter iii. on the use of the words 'contagion' 'infection' &c.). We cannot go very far miss if we understand contagion to be a property of a disease capable of infecting a place person or thing. To quote again 'Consonantly with these views it appears to me therefore that contagion should be entirely confined to that subtle matter, effluvium or emanation (sometimes called contagious principle particles or atoms) which generated the course of a distemper and passing from a person diseased either by contact near approach or the medium of infected materials and whether in a pure or vitiated air is capable of producing a similar disease in one that is sound or acting as an exciting cause in one already predisposed.' (Ibid. pp. 23 24.) Infection may be understood as the result or effect of contagion whether that effect be in a place person or thing. And yet the common usage of the word infection would authorise us in saying the infection infects a phrase that has to parallel in our language." (Ibid., p. 25.) It is not an uncommon question for medical men to have propounded to them by patients or others a correct definition of the terms in question and I think no unprofessional minds a very practical and simple definition is that infection bears just the same relation to contagion as smoke does to fire.

I am, Sirs, yours truly

C. E. MACNAMARA.

'WATCHMAKERS AS OCULISTS.'

To the Editors of THE LANCET.

SIRS.—With reference to a paragraph which appeared in THE LANCET under the above heading we beg to say that no instruction through the medium of a medical man has or will be given on our premises.

We are, Sirs, yours faithfully

London Jan. 10th, 1893.

J. RAPHAEL AND CO.

THE ETIQUETTE OF CALLING

A CORRESPONDENT writes Dr —, in practice at —, takes into partnership Dr —. What is the etiquette as regards the latter as to calling on practitioners—does the usual custom of the new-comer calling on the resident practitioners prevail or not?

*. Certainly. The fact of partnership does not alter the etiquette of the case.—ED. L.

Mr C. T. B. Mauley (Scarborough Hospital) writes — I should be greatly obliged if you will kindly give me your opinion on the following case. An old man of seventy seven years was knocked down in the street and sustained a 'fractured femur (neck of left) for which he was brought to hospital the same day (Nov. 10th, 1892). After remaining in hospital for a period of five weeks he went out on his own account. He then obtained a dispensary ticket (or rather two days afterwards) and I saw him at his own home and found him in the same condition as when leaving hospital. After being at home for five days a hernia (scrotal) which he had had for some twelve years became strangulated. I advised his removal to hospital and helped in conveying him there the next day. He was operated on the same evening and died on the fifth day after from peritonitis and exhaustion. I gave a certificate in accordance with above. The registrar refused it and informed the coroner but he was not satisfied with that and told the friend I had no right to give a certificate. An inquest was held and the jury unanimously agreed that the cause of death was as certified by me and this quite apart from the accident and in spite of a fairly severe cross-examination on the part of the coroner. The members of the staff at the hospital whom I have taken the liberty of asking say I had a perfect right to give a certificate. I shall feel greatly obliged if you will give the valuable opinion asked for.

*. We do not see the reason for an inquest in this case. We think the certificate should have been signed by the resident or operating member of the hospital staff as the last in attendance, for the hernia and its consequences.—ED. L.

Subscriber will find the statistical information which he desires in the Registrar General's Fifty third Annual Report (see Tables 17 18 and 19) published by Eyre and Spottiswoode price 1s. 3d.

Mr F. Tyrrell.—We regret that the grievance referred to should exist, but possibly the publication of our correspondent's letter might increase it instead of remedying it.

AN APPEAL

To the Editors of THE LANCET.

SIRS.—I shall feel obliged if you can find a corner in your next issue for the enclosed appeal. The case is an urgent one as Mrs. Ginders is left practically without means of subsistence. There are many old friends and fellow students of Mr Ginders whose present residence is unknown to the committee and whom consequently we can only reach through your columns.

I am, Sirs, yours faithfully,

St. Mungo's College Glasgow

HENRY E. CLARK.

"By the wreck of the Anchor Line ss. *Roumania* off the coast of Portugal on Oct. 25th 1892 Alfred Gerard Ginders L.R.C.P. and S. Ed. the surgeon to the ship lost his life. He left a widow totally unprovided for who, although willing to work for her living is rendered unfit for any active employment by tibial osteitis, from which she has suffered at intervals since childhood. Mr Ginders had only obtained his diplomas in July last and had consequently no opportunity of making any provision whatsoever for his wife. A small committee has been formed for the purpose of raising such a sum of money as may enable Mrs. Ginders to earn a living in some light employment suitable to her condition of health. The committee consists of—Henry E. Clark, Professor of Surgery St. Mungo's College, Glasgow John Macintyre M.D. Lecturer on Diseases of the Throat and Nose, Glasgow Quintin M. Lennan M.D. Assistant Surgeon, Glasgow Royal Infirmary (treas.). Subscriptions will be received by Dr. M. Lennan, 191 Pitt-street Glasgow and a direct acknowledgment sent."

ERRATA.—On page 36 column 1 line 21 of our leading article last week on 'The University of Edinburgh and Special Diplomas' 'the Act of 1853' should read the Act of 1536.—We regret that by an accident the figure numbered 8 in illustration of Dr John Anderson's article on Clinical and Therapeutical Notes on Two Cases of Aneurysm published in our last issue was wrongly placed. It was as the context obviously shows intended to illustrate the position of the aneurysm in the second case.

During the week marked copies of the following newspapers have been received—*Liverpool Daily Post*, *Leith Burghs Pilot*, *Cambridgeshire Weekly News*, *Eastern Morning News*, *Hull Daily Mail*, *Carlisle Patriot*, *Louth Times*, *Liverpool Mercury*, *Bradford Observer*, *Louth and North Lincolnshire Advertiser*, *Weekly Free Press* and *Aberdeen Herald*, *City Press*, *Leeds Mercury*, *Food, Drugs and Drink Journal*, *Bristol Mercury*, *Mining Journal*, *Reading Mercury*, *West Middlesex Standard*, *Local Government Chronicle*, *Local Government Journal*, *Sunday Times*, *West Middlesex Advertiser*, *Cutler*, *Le Temps (Paris)*, *Weekly Scotsman*, *Bradford Daily Aegis*, *Kelso Mail*, *West Sussex Gazette*, *Hertfordshire Mercury*, *Dundee Advertiser*, *Western Morning News*, *Manchester Courier*, *Scotsman*, *Northern Whig*, *Huddersfield Chronicle*, *South Wales Daily News*, *New York Herald*, *Pioneer Mail*, *Times of India*, *Birmingham Argus*, *West Lothian Courier*, *Law Journal*, *Optician*, *Midland Evening News*.

Clinical Lecture

ON

MYXŒDEMA AND THE RECENT ADVANCES
IN ITS TREATMENT.*Delivered at the Royal Free Hospital*By HECTOR W G MACKENZIE, M.A. EDIN.
M.A., M.D. CANTAB, F.R.C.P. LONDASSISTANT PHYSICIAN TO THE HOSPITAL AND ASSISTANT PHYSICIAN AND
PATHOLOGIST TO THE BROMPTON HOSPITAL FOR CONSUMPTION
LATE MEDICAL REGISTRAR TO ST. THOMAS'S HOSPITAL.

AS we have a patient attending here to-day who has been cured of myxœdema by the administration of thyroid glands by the mouth, as we have at present two patients in the ward in whom similar treatment has been tried, and as there are one or two patients waiting their turn for admission for the same purpose, I think I cannot do better than take the opportunity of recalling to your memory some important features of this extremely interesting disease and of giving you a short résumé of the steps by which the remarkable advance in its treatment has been made and results which have so far been obtained. The process of indeed, through which the treatment of the disease during the last two years (removing it from the all class of intractable diseases which constitute the medicine to the, at present, far too small one in which can be attributed not to the course of nature or intervention of medical skill), forms an important chapter of medical history full of promise and suggestiveness for the cure on similar principles of other maladies and is well worthy of your serious thought and consideration.

I propose, then, first to give you a very brief description of such facts as are known about the disease, which, I hope, may help you to recognise it when you meet with it. It goes without saying that it is useless for you to know how to cure a disease unless you are able to diagnose it. It is specially important for you to learn this now as you have an opportunity of seeing several typical examples of the disease and of comparing one with another, so that you may take with you into practice accurate mental pictures of these cases. For the disease is not a very common one, and you might be in busy practice many years without meeting with a single case, and it is quite possible—nay rather very probable—that unless you take advantage of your present opportunities you will not know it when you see it.

By far the most complete and valuable account of the disease which has yet appeared was published in 1833. I refer to the report of a committee of the Clinical Society of London, under the presidency of Dr Ord, to whom we are indebted not only for the name by which the disease is now universally designated, but also for a great deal of what is known of its symptoms and pathology. This report practically proved the identity of myxœdema, sporadic cretinism and the condition called by Kocher "cachexia strumipriva," which had been observed to develop after the total extirpation of the thyroid gland. It will necessarily rank as the standard work of reference on the subject for many years to come.

The incidence of the disease is in adults usually between thirty and sixty five. At one time it was thought that the female sex alone suffered from it but it is found also to occur in males although more rarely. It occasionally attacks several members of the same family which may result either from some common inherited tendency or from exposure to a common cause. It is invariably associated with atrophy of the thyroid gland, but what causes this atrophy is at present quite unknown.

When the malady is fully developed there is considerable increase in the bulk and weight of the body. The physiognomy undergoes a very marked alteration, and those affected have a strong family likeness to one another their features assuming a placid, mask-like form of expression. The eyebrows are elevated, the eyelids puff and the nostrils broadened. The lower lip is thickened, everted and livid, while the cheeks show a well-defined red patch, contrasting strongly with the pallor of the eyelids. The skin is dry and non-perspiring, rarely shiny and downy. The hair is dry and crisp, and

frequently very scanty not only over the scalp but on the eyebrows in the axilla &c. The subcutaneous tissue is swollen, especially in the hands, feet and legs giving one the impression of œdema, but not putting on pressure. There is usually fullness in the supra-clavicular regions, the gums are swollen and spongy, the teeth carious, the tongue, uvula and soft palate are swollen. The temperature is almost invariably subnormal and the patient suffers considerably from a subjective feeling of coldness. The patient is peculiarly slow in apprehension, thought and action, and is clumsy. Moreover the patient is quite aware of her slowness. Her memory is usually impaired for recent events. She is irritable or placid or alternately the one and the other. Her speech alone is frequently so characteristic as of itself to betray the malady. It is slow, monotonous and deliberate, and there is sometimes so much persistence in idea that there is great difficulty in changing the subject or in terminating the conversation. Sensation may be markedly retarded. Hearing, smell and taste may be impaired or otherwise abnormal. The patient may suffer from frontal or occipital headache, rheumatic pains or numbness or tingling in the extremities. There is frequently a certain amount of inco-ordination and the legs may give way unexpectedly. Sometimes the patient suffers from cramps. The pulse is usually weak, soft and slow. There is a tendency to hæmorrhage from the throat, gums, nose and uterus. The urine is generally of low specific gravity and at a late stage usually contains albumen. All the symptoms undergo aggravation in cold weather. You must not expect that all these symptoms will be present at the same time in every case, but you will find a sufficient number to make you tolerably sure of the correctness of your diagnosis.

The course of the disease is slowly progressive, although in some cases periods of remission have been noted. In one case the disease is said to have disappeared during two successive pregnancies and in another its symptoms diminished under the same circumstances. In one case recovery it is alleged, occurred after two years and a half. Such a result is, however, most unusual. As a rule while life lasts it is a burden. Many of the patients end their days in asylums. Some are carried off by phthisis or other intercurrent disease, while the remainder die sooner or later from the disease itself.

The characteristic morbid changes found after death are few. As a rule the subcutaneous fat and often that elsewhere is over-abundant. Passive effusions into the serous cavities and slight anasarca are not infrequent. The thyroid gland is in every case atrophied, as you see in the specimen I am able to show you from the museum. Although the kidneys, lungs, heart or arteries may be diseased there is no change in them peculiar to myxœdema. Distinct histological changes are limited to the skin and thyroid gland. In the skin there is swelling of the epithelium of the tubes of the sweat and sebaceous glands and obliteration of their lumen, with nucleated fibrous growth in the surrounding tissues. In the thyroid gland in the earlier stages there is a small celled infiltration of the walls of the vesicles, accompanied or followed by epithelial proliferation in their interior and in the later stages the gland becomes converted into a delicate fibrous tissue, in which the remains of the vesicles are represented by clumps of small round cells.

As you are doubtless aware the name "myxœdema" was given to the disease by Dr Ord on account of the excess of mucin found in the swollen subcutaneous and other connective tissues. This excess was very striking in Dr Ord's original case and it has been confirmed by observations in cases of experimental myxœdema and in some human cases, and although examinations of other cases have shown that at the time of death mucin may not be in excess there is little doubt that it is an essential feature at a certain stage of the disease. Excess of mucin has been found in internal organs, such as the lungs, spleen and parotid, as well as in the subcutaneous tissue.

In regard to treatment, at the time of the Clinical Society's report little could be done to alleviate the disease, little or no hint to check its progress. Tonics, jaborandi and nitro-glycerine were given to improve the appetite and to act upon the skin and were reported to have produced temporary benefit. For such patients as could afford it, migration to warmer climates during the winter was strongly recommended. But the labours of Dr Ord, Professor Horsley, Dr Semon and others had brought the knowledge of the disease to such a pitch that a cure for it was no longer wanting. Dr Ord in his original com-

munications on the subject had called special attention to the atrophic condition of the thyroid gland. Dr Semon, struck by the resemblance of the train of symptoms observed by Kocher to follow after complete thyroidectomy, had first brought the matter forward in this country and by indefatigable energy was principally instrumental in collecting the vast amount of evidence tending to prove the identity of this cachexia with myxœdema. Professor Horsley, by numerous laborious experiments, showed the close resemblance of the dyscrasia produced in some of the lower animals by the removal of the thyroid gland to human myxœdema. The result of these investigations amounted to a proof that the one thing lacking in the myxœdematous condition was a functionally active thyroid gland. Professor Schiff and others after him had shown that the evil effects of thyroidectomy in animals could be diminished by transplanting a thyroid gland previously to the operation. This important observation Professor Horsley followed up by suggesting a similar procedure as a possible means of arresting the progress of myxœdema. This suggestion was accordingly soon carried into execution and the operation was attended with striking but unfortunately only very limited and temporary improvement. The difficulty was to effect the survival of the transplanted gland in its new position and what actually happened was its absorption by the surrounding tissues. The fact of improvement at all was, however, encouraging. The benefit resulted so soon after the operation that it could be explained only by the absorption of some substance actually present in the gland at the time of transplantation. I have not seen any explanation of the curious fact of the great amelioration of the disease during pregnancy to which I have already alluded, and it seems to me likely that the thyroid of the fœtus supplied for a time the place of that of the mother, the benefit naturally terminating with delivery.

The next step was the employment of hypodermic injections of a glycerine extract prepared from thyroid glands, first in animals after thyroidectomy, and secondly in myxœdema. The fact of its usefulness in animals, with which the names of Vassale and Gley are associated, suggested to Brown Séquard and d'Arsonval its probable utility in myxœdema, but, apparently quite independently, the idea of its use seems to have occurred to Dr George Murray of Newcastle who was amongst the first, if not actually the first, to employ this mode of treatment, and certainly the first to prove its success. By Dr Murray's method very beneficial results were soon obtained by other physicians, and numerous reports of cases successfully treated by it appeared in the medical journals and in the transactions of the medical societies. But, excellent as these results were, the method was not altogether free from objection. Some sensitive patients shrank from the hypodermic needle. Unless the fluid used for injection was absolutely aseptic subcutaneous abscesses and indurated swellings were apt to follow the injections. It was also found that rather alarming symptoms, such as lividity, pain, loss of consciousness, temporary loss of power in the extremities or general muscular spasm, sometimes supervened during or immediately after the administration of the injection. The difficulty with which the physician had to contend when he prepared the extract himself has been removed and the risk of the occurrence of septic abscesses has been greatly lessened by the enterprise of Messrs Brady and Martin of Newcastle, who now prepare weekly a sterilised extract which they supply at a moderate cost considering the care required in its preparation. Putting the risk of local effects apart, however, I cannot but consider the even rare occurrence of such unpleasant symptoms as I have mentioned a serious drawback when a long series of injections has to be taken into account.

The next advance, and a very important one, is closely connected with the patient who is hereto day to all intents and purposes cured of myxœdema. This was the discovery which I made that the administration by the mouth of the thyroid gland or of a preparation derived from it served the same purpose as hypodermic injections of thyroid extract—in fact, had all its advantages without any of its disadvantages. By a curious coincidence the same discovery was made about the same time quite independently by Dr E L Fox of Plymouth and an account of his case appeared simultaneously with that of mine.¹

Some of you may remember my patient when she first came under my care three years ago. She was then thirty seven years of age but from her appearance she might have very well passed for fifty. At that

time the disease had been fully established for two years and a more typical example of it than she presented you could not possibly have found. I admitted her to this hospital in February, 1890, in hopes that an opportunity might present itself of carrying out Professor Horsley's then recent suggestion of transplanting a thyroid gland, an operation which Mr Battle, who saw the case in consultation with me, undertook to perform as soon as possible. While we were waiting for a suitable case from which to transplant, the patient became impatient and went home. She continued under my care, however, and attended very regularly as an out-patient, receiving benefit, as she thought, from infusion of jaborandi and tonics. Shortly after the publication of Dr Murray's paper I admitted her again as an in-patient and made arrangements to give her the benefit of the new treatment. Through indisposition I had to give up work for a short time, so that it was not carried into effect, and again the patient went home. In July last year she was admitted for the third time and the success which has followed what was an untried treatment more than compensates for the disappointment on the two previous occasions.

During the two years and a half we had been watching the patient the disease had been slowly but steadily progressing. Whether our treatment by jaborandi, tonics, rest in bed, massage and the other means we had employed had prevented a more rapid progress we cannot say. Certainly she had been temporarily benefited a little by her two admissions and she herself had some faith in the efficacy of the medicines prescribed for her. Many of you will remember her condition before we started the new treatment, her great bulk, heavy expression, her coarse swollen features, thick protruding livid lips, broad nose, flushed cheeks, contrasting with her waxy yellow complexion, her bald and scaly scalp, large clumsy hands, harsh dry unperspiring skin, œdematous lower extremities, her incapacity for exertion and slow monotonous speech, the general feebleness of all her mental processes, her constantly subnormal temperature, and all this in the middle of summer, the most favourable season for patients suffering from this disease. You see her now six months later a bright, active, even lively woman, by no means too bulky, with little or no trace of the former swelling of the face, with healthy complexion, luxuriant growth of hair covering her scalp, hands normal in appearance, moist supple skin, extremities free from œdema, capable of all ordinary exertion, quick in speech, and in full possession of all her mental faculties.

Let me remind you of the manner in which this transformation has been brought about. When I admitted the patient last July it was with the full intention of treating her by the hypodermic method. I was, however, deterred from doing so by observing that in one patient treated in this way a local abscess and pleurisy followed, while in others local discomfort and indurated swellings occurred. It was not long before I determined to try a new method and some of you seemed a little surprised when I wrote on the bed ticket "two sheep's thyroid glands to be obtained fresh from the butcher and to be given to the patient finely minced every day." I purposely ordered a full dose because I thought if the glands were active at all when given in this way the action would be much slighter than when the juice was given hypodermically. You may remember we had some difficulty in getting the butcher to comprehend what we wanted. At first he sent the thymus then he sent the trachea with nothing on it, but eventually he provided the trachea with the gland covered by the muscles intact. As you may later on have the same difficulty to contend with those of you who have not already done so should take the opportunity of acquainting yourselves with the appearance and situation of the sheep's thyroid gland. The isthmus is so rudimentary that you may easily overlook it, but you will have no difficulty in recognising the oval shaped darkish red lobes underneath the muscles on each side of the trachea, a little smaller than the normal size of the lobes of the human gland. The effect of the administration of the minced glands on the temperature and on the sensations of the patient was almost immediate. The temperature became normal or even a little above normal while a comfortable sensation of warmth pervaded the patient's body. Although I had ordered the glands to be given every day she did not have them nearly so frequently, as they were not given if there was the least suspicion of staleness about them. During the first fortnight the patient had had eight thyroids and two drachms of thyroid extract by the mouth. By the end of that time her appearance had very considerably altered for the better. Her

pulse rate, however, had quite doubled its former rate, having risen from an average of 56 to 116. The rapidity of pulse persisting, I discontinued the thyroids for a time, when the rate gradually fell to about 80. The patient from time to time was troubled with vomiting, and this—as it sometimes occurred after the thyroid glands—I was at first inclined to attribute to the knowledge she had that she was taking something raw and the nausea induced thereby. Experience of other cases has, however, convinced me that vomiting, like increased frequency of the pulse, is a sign that too much of the remedy is being administered and is the indication for its temporary cessation. If the remedy is pushed vomiting may become an exceedingly troublesome complication. The progress of the patient was in every other way completely satisfactory, and the rapid manner in which improvement manifested itself was one of the most striking features of the case. The change in the face was an early result. It seemed, indeed, as if a mask had been removed from it. The alteration in the hands and feet soon followed. About six weeks after the treatment was started the hands and feet desquamated as completely as after scarlet fever and a delicate, soft skin replaced the former thick, coarse cuticle. With the rapid loss of bulk there was an equally rapid loss of weight, so that there was a difference of two stones in two months. The improvement in the mental condition and in the speech set in almost as early as the physical changes. One of the most striking changes was that on the hair and this became noticeable a little later than the other events. About two months after the treatment was started, you may remember, we found a very thick growth of hair was beginning to appear on the scalp, and now from the different length of the new and the old hair you can see what a quantity of new hair has grown. When the patient commenced to get about again after being confined to bed so long she was for a time troubled with slight oedema of the feet and legs, which you will remember she had to a much greater degree at the time the treatment was commenced. The oedema, however, soon disappeared as the heart got stronger. You must bear in mind that the heart has to recover as well as the rest of the body, and that there is a possible danger of syncope if unwonted muscular exercise is engaged in too early. We must therefore insist that for a time the convalescent patient should take things easily and lead a more or less inactive life. During the first month or two the mode of administration of the gland which we adopted was extremely simple. I have already mentioned that the finely minced gland was taken with a small quantity of brandy or beef tea. Latterly the nurse has prepared it a little differently. After mincing it she lets it stand for about half an hour with a few teaspoonfuls of water, and then strains the whole, squeezing the juice through a piece of linen or muslin. The expressed fluid is added to some beef tea. This home-made extract appears sufficiently potent to keep our patient in good health, although she only has it once a week. The gland has also been given lightly fried in some cases without destroying its good effects, but it is extremely probable that thorough cooking will be found to render it inert.

Later experience has confirmed my surmise that much less of the remedy is required than I at first employed. A gland or half a gland or the extract therefrom twice a week is as much as it seems advisable to commence with, and at a later period the same amount once a week appears to be sufficient.

In order to have the remedy in an ideal form it should be palatable, easily procurable and cheap. It would therefore be a great desideratum to be able to manufacture on a large scale a permanent preparation from thyroid glands in a less costly manner than that necessary in the case of the extract prepared for hypodermic use. Mr White, the able pharmacist of St. Thomas's Hospital has for some time been working with this end in view and he has succeeded in preparing a powder which is tasteless, keeps perfectly, and, as far as it has been tried, apparently answers very well. One of the patients in the ward is being treated with this preparation and her progress so far is perfectly satisfactory. Should this powder fulfil our expectations then I think the treatment will have advanced as far as we can possibly expect it to do.

It was natural that the thyroid treatment, having proved so successful in myxœdema, should be tried in the other disease which is so closely related to the thyroid gland—namely Graves' disease or exophthalmic goitre. It has long been a moot point whether the thyroid enlargement was simply one of the phenomena of that disease or whether it was associated with a perversion of the function of the gland

which was as much the cause of the other symptoms as the atrophy of the gland is the cause of those of myxœdema. In my lectures on Graves' disease, published in THE LANCET of Sept. 13th and 20th, 1890, I considered this question and gave reasons for my opinion that the change in the thyroid was only a concomitant symptom and not the basis of the disease, which I looked upon as being essentially dependent on changes in the central nervous system. If, however, the disease were due to a morbid condition of the thyroid it certainly could not be of the nature of a deficient supply of juice, but would rather be an over secretion of either normal or perverted juice. If the symptoms of the disease owed their origin to a perverted secretion the administration of thyroid juice might reasonably be expected to benefit, but if they were caused by an increased secretion it should intensify them. I have given the thyroid treatment a fair trial in two cases of Graves' disease under my care, one of which is at present in the ward. In neither case has it appeared to have any effect at all on the symptoms or course of the disease. In both cases I gave the patients the minced gland by the mouth sufficiently frequently and for a sufficiently long time to produce an effect, if any effect were capable of being produced. We must therefore look in other directions for the cure of Graves' disease.

The great distinction between the thyroid treatment of myxœdema and the method of treatment recommended by Brown Séquard for a great variety of diseases, from cancer to hysteria, with which method it has been compared, is the thoroughly rational and scientific basis of the former. It is on such a foundation we must look for advance. The more thorough our acquaintance with the pathology of disease the more hope is there for the discovery of a cure. I feel sure that the cure which has been found for myxœdema will before long be followed by the discovery of as potent remedies for what are at present thought quite as incurable and hopeless diseases as myxœdema itself until very recently has been considered.

THE SENSITIVENESS OF THE PERITONEUM

By LAWSON TAIT, F.R.C.S. EDIN. &C.

THE question of the sensitiveness of the peritoneum was raised in a discussion in THE LANCET in December last by my having given utterance to opinions in the following sentences: "My own experience is that the slightest touch by the finger or sponge or instrument applied to almost any part of the peritoneum in a patient who is not only not sensible, but who is partially or even almost completely anaesthetised in the sense that he is only just beginning to come out of the chloroform, at once gives rise to movements of the abdominal wall and limbs which indicate pain. I have very rarely been obliged to put my fingers within the peritoneum of a patient not under an anaesthetic, but these few experiences resulted in such agony to the patients that it became evident that modern abdominal surgery without anaesthetics would be an absolute impossibility. All these cases were instances of serious and sudden hæmorrhage, where to have waited for unconsciousness would have been to have waited too long. The agonising pain of hæmorrhage into the peritoneum—an experiment tried very often by Nature herself, as quoted by Dr Gee—is quite confirmatory of the facts as I have seen them. However, these are both points of much interest, upon which the attested experience of other surgeons ought to be given." My interpretation of these phenomena was controverted by Dr C. S. Sherrington, who said in a letter published in THE LANCET of Dec. 17th, p. 1417, that "the peritoneum was shown by Haller in the experiments of his famous essay to be quite insensitive to mechanical and many other modes of excitation", and further that "the healthy peritoneum is a membrane sentient under mechanical interference is a dictum which Mr Tait will, I imagine find as difficult to substantiate before the surgeon as before humble followers of Haller's science like myself."

It is of course, perfectly possible for any human observer to be mistaken in his records, yet I could hardly believe that I could stand alone in the observation of what seemed to me facts of almost weekly occurrence, and I suggested that it might be that my interpretation of the facts was mis-

taken So persistent, however, was my experience in the matter that I had come to look almost with terror to the performance of any operation in which the anæsthetic was administered by anyone not accustomed to give anæsthetics in the performance of abdominal operations. When it happened that I had to perform an operation under such circumstances I found it certain to be the result that I had to press the administrator to push the anæsthetic more deeply than he was disposed to do, and that as my fingers got more and more deeply inserted amongst pelvic viscera not at all in association with parietal peritoneum the necessity became greater for pushing the anæsthetic, and, whatever the explanation may be, it will not be found in the statement that one part of the peritoneum is insensitive whilst another is sensitive. Since writing the letter to which I allude I have had to perform several operations where the anæsthetist has been called casually or in an emergency to assist and have therefore had opportunities of deliberately watching the phenomena I have already described, and I have found that my fingers on touching the back of the uterus, folds of intestine, great omentum, the front of the rectum, the pelvic wall and the posterior parietal surface, give rise to such movements in incomplete anæsthesia that I had to insist on deeper insensibility. I am therefore satisfied that, whether these movements are indicative of pain or not, the facts show that all parts of the peritoneal surface, or at least such as usually come in contact with the fingers of the operator, are capable of exciting precisely the same phenomena. The interpretation which I put upon these facts that the movements of the patient are due to pain may be wrong, just as the view that some of us hold that the wriggings of a worm impaled upon the fisherman's hook are indicative of extreme agony on the part of the worm may be perfectly mistaken, for the worm may be really enjoying it, but when I have the experiments of nature in acute peritonitis and accidental effusion into the peritoneum causing pain to a degree which amounts to agony, I am not disposed to accept any mere assertion that the movements are reflex and that the peritoneum is insensitive.

Whatever be the true explanation, I am glad that the matter has thus been brought prominently under notice, and for the following reasons. I think the facts as they are substantiated by many of my correspondents show that here as elsewhere it is perfectly impossible to accept the conclusions derived from experiments on animals as applicable to man even when they have such an authoritative origin as the celebrated Haller. It is probable also that it is dangerous to accept the conclusions derived from one human patient as applicable to another of the same kind. Again, it seems to me a wholesome humiliation for all of us to find that, in a matter of physiology so simple and on a point of surgery so cardinal, our ignorance is even now profound and, I venture to think, discreditable. The discrepancies evident in the conclusions of my various correspondents show that our habits of observation are very inexact and our tendency to trust to the teachings of authority far too great. Doubtless within the next few months the real facts of this important point will be definitely settled and the erroneous conclusions of one side or the other will be corrected.

As a method of obtaining evidence on the question I asked my secretary to issue the following circular to all the surgeons of Great Britain and Ireland whose names are familiar in connexion with abdominal work. Unfortunately he did not preserve a copy of the list, but it contained over thirty names. There are many who have not replied upon whose evidence I depended largely for a settlement of the question. As far as it goes the evidence does not settle it. The funniest part of the evidence is that of my two assistants, the brothers Christopher and Charles Martin. Their opinions are based on precisely the same cases as are my own. Christopher agrees with me, whilst the interpretation of the phenomena by Charles differs from ours entirely.

"The Crescent Birmingham, Dec 17th 1892.

"MY DEAR SIR.—A question has arisen respecting the sensitiveness or otherwise of the human peritoneum.

"According to my own experience, if the fingers of the operator enter the peritoneum before complete anæsthesia has been arrived at, strong muscular contractions and active resisting movements of the patient inevitably occur, and the operative proceedings have to be suspended until profound unconsciousness is attained. The same phenomena occur if by any means the patient is allowed to become partially conscious during the operation.

"I have on a few occasions been obliged to insert my

fingers into the peritoneal cavity in grave emergencies without waiting for an anæsthetic, and the screams of the patient have been almost deterrent. Perforation of any part of the intra-abdominal viscera with effusion of blood or intestinal contents in a conscious patient has, in my experience, always been followed by pain of such instantaneous occurrence and such violence that I regarded it as due to the contact of the foreign matter with the peritoneal nerves.

"My conclusion from these facts has been that the human peritoneum is extremely sensitive, and I should be glad to know if you agree with this conclusion. In the event of your not agreeing with it may I venture to hope that you will give me your reasons, so that we may obtain some conclusive evidence upon a matter so important?

"I am, yours very sincerely,

"LAWSON TAIT."

Dr W Sinclair Thomson writes "In reply to your wish for my opinion 'as to the sensitiveness or otherwise of the human peritoneum,' I beg to state that I believe it to be extremely sensitive."

Mr Alban Doran writes "There can be no doubt that the reflex sensibility of the peritoneum is considerable. This is seen by the sudden contractions of the recti when the peritoneum is touched, the patient not being completely under the influence of the anæsthetic. This effect is most evident when a sponge is used or when the water employed for flushing is too hot or too cold."

Dr C J Cullingworth writes "With regard to the sensitiveness of the healthy peritoneum my experience is entirely at variance with yours. It has never happened to me to witness the phenomena you describe, and I am strongly of opinion that you will find, when your attention is directed to the point more closely, that you have in this instance made an erroneous observation and credited the peritoneum with a sensitiveness that really resided in other tissues."

Dr Heywood Smith writes "I fear I cannot throw much light on the question of the sensitiveness of the peritoneum. I cannot recall any instance when I have been in a position to make any observation when the patient has only been partially anæsthetised. Perhaps this is because I have not looked for it. In future I will bear it in mind."

Mr J Greig Smith writes "It is quite impossible to answer in one word your question as to the sensitiveness of the human peritoneum. To begin with, you must distinguish between parietal and visceral peritoneum. Visceral peritoneum covering the intestine is practically devoid of sensibility to ordinary traumatic causes. This is beyond dispute. You may puncture, stretch, cut or completely resect the intestine without the patient feeling it. A form of words which I often employ in answering a patient's question as to whether the proceeding will be painful is that it will be felt 'no more than paring the nails.' It is quite easy for you or any friend of yours to verify the truth or falsity of this statement on patients of mine almost at any time. I publicly teach this, and publicly demonstrate it. At present I can let you talk with a patient from whom six inches of cancerous intestine were removed while she had no anæsthetic whatever. The parietal peritoneum, supplied by ordinary nerves of sensation, is of course sensitive to pain. The finger passed through a parietal incision comes in contact with sensory nerves in skin, muscle and peritoneum and sets up painful reflex muscular spasm as well. Certainly such a proceeding is painful, and no doubt some of the pain is from parietal peritoneum. It is almost impossible to have an effusion of blood, bile, intestinal or stomachic contents which does not overflow parietal peritoneum and so cause pain. Amongst the pelvic organs, where ordinary sensory nerves are abundant everywhere, sensitiveness is certainly present. And, again, a furious intestinal peristalsis, which may be set up by numerous irritants outside and inside the gut, is very painful. A gastric ulcer is painful when pressed upon and when gastric juices come into contact with it. Incision and suture of a healthy stomach are painless. You may wash, stow away and, if you like, puncture the extruded intestines of a human being without causing pain, but a recurrent inflammation of the vermiform appendix is extremely painful. My friend and former dresser, Dr Edgeworth, pathologist to the Bristol Royal Infirmary, will tell you the reasons better than I can. He has been doing 'experimental research' in Leipzig and elsewhere, and has published various monographs on the subject. His researches explain my clinical experience. Lastly, is it possible to isolate the pain felt in the peritoneum proper from the pain felt in an underlying organ? This may

be proved by 'experimental research,' but it cannot be proved by arguing.

Mr J Bland Sutton writes "To your question as to the sensitiveness or otherwise of the human peritoneum I enclose the following reply. 1. Healthy peritoneum is insensitive to such stimuli as evoke painful sensations in skin and mucous membrane—e.g., pin or needle pricks, incisions by knife or scissors and to digital manipulations. 2. Inflamed peritoneum, especially when covering intestine, is acutely sensitive. On two occasions I have introduced my finger into the track of a drainage-tube after operations on the pelvic organ. In each instance when my finger touched a coil of bowel, the peritoneal covering of which was inflamed, agonising pain was experienced by the patient. I once transfixed and tied a small protruding piece of inflamed omentum, the patient being conscious. The proceeding caused great pain.

Mr A. W. Mayo Robson writes "To answer your question by a simple 'yes' or 'no' is impossible, as it would be a 'yes and no'—i.e., I have found the parietal peritoneum to be decidedly sensitive to pain, whereas the visceral peritoneum I am equally certain is insensitive. This I think, easily accounted for, as the parietal peritoneum receives branches of the sensory nerves which supply the parts over it whereas the visceral layer only receives twigs from the sympathetic nervous system. The sensitiveness of the peritoneum is proved by the pain on inserting the finger without anaesthesia, which I have done only on two or three occasions, as also by the agony of perforation. The insensibility of the visceral peritoneum I have often proved in the second part of inguinal colotomy gastrotomy and similar operations done without an anæsthetic."

Mr J Stuart Naume writes "I agree entirely with your statement of facts. If, however, a man makes an incision a foot or a yard long in the abdominal walls or if he is dealing with a case nearly moribund, I think he may be excused for not noticing the phenomena you mention. There are a few more details which you might throw together in an unanswerable form shortly and dispose of the question. I hope to send you to-morrow the statements of two of my anæsthetists who have noticed what you refer to and who have been present at scores of my public cases."

Mr T R Jessop writes "The opportunities of testing this question have been few with me, but I have always been, and still am, under the impression that the peritoneum is not a very sensitive organ. In opening the sigmoid after an inguinal colotomy I never give an anæsthetic, and never that I remember has a patient expressed any suffering whether I have used scissors or cautery. I have several times seen the peritoneum bathed with urine and blood in cases of ruptured bladder in which pain has been absent or nearly so. An inflamed peritoneum is not painful unless indeed, it be stretched as in peristalsis or pressed upon as by the fingers or in distension. It is not my experience that extravasation of feces in rupture produces excessive pain. I have twice emptied the peritoneal cavity of many pints of feces where pain has not been a prominent symptom. May not the 'strong muscular contractions' and 'screams of the patient' have been due to the contact of your fingers with the abdominal wound? I have no experiments bearing more directly on the question than the above and my deduction may be wrong."

Dr James Murphy writes "In reply to yours I have never opened the peritoneum except when the patient has been under an anæsthetic, but in all my cases of gastrotomy and colotomy where I am able to do the operation in two stages in opening the stomach or colon the nurse puts a handkerchief over the patient's face. I did one yesterday, and I have asked the patient particularly and he assures me that he felt no pain and had no idea of what I had done until I told him. Another patient whom I did last week gives me the same assurance.

Dr J Rutherford Morrison writes "Perhaps the best way of answering your question of Dec. 20th will be to relate my experience. 1. In inguinal colotomy I find I can cut out the exposed sigmoid flexure and apply ligatures to bleeding points on it without causing pain. In two cases I have opened the intestine with the thermo-cautery without causing more than a disagreeable sensation. In two cases I have rushed and freely handled escaped intestine, the patient being conscious without much pain. From this experience my belief would be that the visceral peritoneum is not endowed with great sensibility. In one case recently I put my finger into a wound in the linea semi-

lunaris and passed it down to Douglas' pouch, the patient being a sensitive man and conscious. To assure myself that my finger was in the peritoneal cavity I swept it over the parietal peritoneum—round the wound. Very little complaint was made. In this case the parietal peritoneum was not very sensitive. A patient whose undescended testicle into a hernial sac I had excised bled into his peritoneum from slipping off the cord. He had little pain. A young man whose distended gall bladder I punctured with a hypodermic needle for exploratory purposes and whose gall bladder emptied into the peritoneal cavity within half an hour had not excessive pain. I have several times operated on ruptured ovarian cysts but could get no history pointing to a definite time of rupturing. Here, of course, there may have been some leakage from a small cyst. In cases of perforating gastric ulcer I have observed what you mention, great pain, but I have seen a case of perforation of the cæcum and the abdominal cavity flooded with feces without marked pain. There can be no question, I should say, about the depression and agonising sensation of impending death when foreign bodies are quickly introduced into the peritoneal cavity, and my experience would incline me to the view that this is more common than severe pain. I trust these short notes may be of service in your interesting inquiry."

Professor A. R. Simpson writes "As to the sensitiveness of the peritoneum I have no good grounds for forming any very decided opinion, though I am quite ready to receive any demonstration of its sensitiveness. The only case in which I saw intestinal coils protruding through a section wound—where some stitches had given way some twenty-four hours after operation—the patient complained of no pain when the bowel was touched. May it not be that visceral peritoneum covering organs supplied from the sympathetic system is not immediately sensitive, whilst the parietal peritoneum in pelvis and elsewhere covering structures supplied from the cerebro-spinal system of nerves may be exquisitely sensitive?"

Mr John D Malcolm writes "I am in receipt of yours of the 17th inst. concerning the sensitiveness or otherwise of the human peritoneum, but I regret that I am not prepared to give you any opinion on the subject at present."

Dr M Cameron writes "I am quite opposed to your idea of the peritoneum being highly sensitive. In many operations near the finish, when anæsthesia was not being pushed, neither when touching the peritoneum nor yet when passing needles from within outwards did the patient complain until the skin was reached when she was restless. Besides, after the removal of the drainage-tube I have passed a curved probe and the patient never manifested any sign of pain when the probe point was pressed upon the peritoneum. However, it is worthy your investigation, and I shall look for new light upon the subject."

Dr W J Smvly writes "The impression left upon my mind is that the peritoneum is not very sensitive to touch. I have not had many opportunities, however, for observation. On one occasion when I operated for a ruptured tubal pregnancy the woman was so collapsed that I only ventured to give her a whiff of chloroform when cutting through the skin and again when inserting the sutures, but though she winced then she made no complaint during the rest of the operation. In two cases in which I introduced a drainage tube into the peritoneal cavity on the third day after abdominal section the patients complained of pain when a stitch was removed, but neither the introduction of my finger nor of the tube appeared to cause any pain. I have often observed what you mention that though patients may remain quite passive during the section of the abdominal wall they writhed and draw up their legs when the hand is introduced into the cavity but this I have regarded as reflex action which persists after complete insensibility to pain, and the same thing occurs when the fingers are introduced into the rectum."

Dr G Granville Bantock writes "I have seen the correspondence—some of it, at least—which has taken place in the medical journals on the question of the sensitiveness of the peritoneum. My experience agrees with yours—viz., that if the fingers of the operator enter the peritoneum before complete anæsthesia has been arrived at strong muscular contractions and active resisting movements of the patient inevitably occur and the operative proceedings have to be suspended until profound unconsciousness is attained. This is more particularly observed in the case of using a sponge. I presume every operator of experience will tell you that this has frequently been observed by him. Nor will

anyone question your further remark that 'the same phenomena occur if by any means the patient is allowed to become partially conscious during the operation' When, however, you say that 'on a few occasions' when you have 'been obliged to insert' your 'fingers into the peritoneal cavity in grave emergencies without waiting for an anæsthetic' 'the screams of the patient have been almost deterrent,' then I must say my experience does not agree with yours. In a case of bursting open of a wound in a fat subject in the effort of coughing a day or two after the removal of the sutures, during the handling of the peritoneum in sponging (cleaning) the extruded intestine and inserting sutures there was undoubted sensitiveness manifested, but not such as to require the use of an anæsthetic. In this case, of course, the peritoneum was quite healthy. The same remarks apply to a case in which I had to open the wound and reinsert sutures on account of protrusion of omentum through a tube-hole (this case also furnished positive evidence that a drainage-tube may leave behind it absolutely no trace of its employment). But when we come to deal with cases in which there is peritonitis then the sensitiveness of the peritoneum is beyond dispute. I have met with several cases bearing on this point and in which the pain was undoubtedly very great. Nor do I imagine that anyone will dispute your assertion that 'perforation of any part of the intra-abdominal viscera' is 'always followed by pain of such instantaneous occurrence and such violence' as to lead anyone to regard 'it as due to the contact of the foreign matter with the peritoneal nerves.' One correspondent has related his experience in cases of colotomy (inguinal) as proving the non-sensitiveness of the peritoneum. He says that in those cases where the intestine is not opened till a day or two after the operation you may cut away the intestine as you please without signs of suffering on the part of the patient. He evidently sees no difference in the behaviour, if I may use the expression, as between healthy and strangulated tissues. On the whole, therefore, you will see that my experience closely corresponds with yours with the exception stated."

Dr William Travers writes "My experience on the very few occasions in which I have had to deal with the normal human peritoneum in the unanæsthetised patient has led me to consider this membrane very insensitive—notably so in two cases of incised wounds of the abdomen and large intestinal protrusion which had to be returned through enlarged openings, here, too, the peritoneum may be presumed to have been in a healthy condition. Of course the amount of collapse existing in these and, indeed, probably in all cases that we now deal with without an anæsthetic may have had something to do with the seeming insensitiveness. But, again, I have also noted and expressed to those present—in cases where the patients have been allowed to 'come round' from the anæsthetic ere the 'sewing up' was finished—that the passage of the needle through the skin apparently gave rise to much more suffering than its passage through the deeper tissues, including the peritoneum. Once more, I have on several occasions—three times—indeed, within the last six months—seen cases immediately after perforation of the bowel had taken place and noted that the marked symptoms had been immediate and very severe collapse without evidence of the instantaneous acute pain you speak of, nor have the patients after partial recovery from the collapsed condition complained much of early acute pain. With all this, I do not pretend to have hitherto given this subject the attention it certainly deserves or in a manner to justify my experience being of any value as evidence for or against."

Dr Christopher Martin writes "My opinion, based on the observation of nearly 1000 abdominal sections, is that the healthy human peritoneum is markedly sensitive and that the parietal is more so than the visceral. In the few instances in which I have been compelled to introduce my finger into the peritoneal cavity of a patient not anæsthetised there has been great suffering. For the satisfactory performance of an abdominal section very profound anæsthesia is necessary. Where the patient is only partially 'under' any intra-peritoneal manipulations excite unmistakable evidences of suffering the act of sponging the membrane being particularly painful. On the other hand, I am of opinion that peritoneum which is thickened chronically inflamed or diseased, or which has been exposed for some hours to the air, is nearly insensitive. In cases of inguinal colotomy (where the bowel is not at once opened) the exposed portion of the peritoneum quickly becomes thickened and loses its sensibility, and may be incised with knife or thermo-cautery without the slightest pain."

Dr Charles Martin writes "I have pleasure in replying to your letter of Dec 17th last. The opinion I have formed of the sensitiveness or otherwise of the human peritoneum, based largely on the observation of about 300 abdominal sections, is that it is very slightly, if at all, sensitive. True it is that, if a patient be not deeply anæsthetised, intra-abdominal manipulations may give rise to movements indicative of suffering, but I do not believe that stimulation of the peritoneum is the cause of that suffering, but that it is caused by the fingering of the abdominal wound or the manipulation of sensitive structures beneath the peritoneum. At the commencement of an operation, if the patient be insufficiently anæsthetised, movements are frequently occasioned by incision through the skin, but very rarely by division of the deeper structures, including the peritoneum. Similarly at the close of the operation, I have observed that, when the patient has been allowed 'to come out' prematurely, pain is occasioned by the insertion of the suture needle through the skin, but not by its passage through the peritoneum. Where perforated glass drainage-tubes are used, tags of omentum frequently insinuate themselves through the holes and become imprisoned, and I have on several occasions had to expose and divide these bands and change the drainage-tube, and no pain was occasioned that I could not ascribe to the necessary disturbance of the wound. I have seen two cases of hysterotomy, the wound in the uterus being closed by interrupted silkworm gut sutures, whose stiff ends projected above the smooth surface of the fundus into the peritoneal cavity in a bristling row. One of these patients, some months later, underwent the operation of vaginal hysterectomy for the cure of menstrual suffering, and the sutures were then seen to project as prominently as they did at the time of the first operation. The other case recovered completely and has since been free from pain. In neither case has there been any pain which I could reasonably ascribe to the mechanical irritation of the various peritoneal surfaces, against which the ends of the silkworm gut sutures must constantly have been rubbing. Again, it is a fact that exploratory abdominal sections, and even ovariectomies, have been performed without a general anæsthetic¹ after the mere injection of cocaine into the abdominal wall, and I have myself without any anæsthetic incised the abdominal wall, introduced my finger and explored the cavity without more pain than would be caused by the wound itself. It is difficult for me to conceive of such proceedings being possible were the peritoneum possessed of other than a very low degree of sensibility."

The Crescent Birmingham

THE RELATIONSHIP BETWEEN THE PHRENIC AND INFERIOR LARYNGEAL NERVE,

WITH AN EXPLANATION OF THE CIRCUITOUS COURSE
TAKEN BY THE LATTER.

BY THE LATE HERBERT DAVIES, M.D. CANTAB,
F.R.C.P. LOND.²

LATE CONSULTING PHYSICIAN TO THE LONDON HOSPITAL AND FORMERLY
FELLOW OF QUEEN'S COLLEGE, CAMBRIDGE.

I AM not aware that any explanation has yet been offered by physiologists to account for the circuitous course taken by the inferior or recurrent laryngeal nerve in the bodies of man and animals generally. The reason for its curiously winding and lengthened track, which contrasts with the direct path of the superior laryngeal nerve, may, however, I believe, be inferred from a study of the parts which the nerve supplies and the rationale of its destination will be found to exemplify that exact adaptation of means to ends which is invariably present in the animal economy. As the act of inspiration is mainly performed by the descent of the diaphragm and by the opening of the rima glottidis to admit the incoming air, it is clear that the respective muscular actions which cause the lowering of the one and the opening of the other must be synchronous for the lowering of the diaphragm without the simultaneous widening of the glottis would cause but a forcible and stridulous blast into the trachea and an imperfect supply of air to the lungs, while the dilatation of the rima previously to

¹ Not by me—L. TAIT.

² A posthumous paper communicated by his son, Arthur T. Davies, M.D. Cantab.

the commencement of the descent of the diaphragm would evidently lead to no useful result. If, then, this reasoning be admitted to be correct it must necessarily follow that the two mandates which simultaneously leave the respiratory nerve centre in the medulla to effect the simultaneous actions of the diaphragm and muscles of the rima must arrive at their respective destinations synchronously. The vagus centre is the regulator of the respiratory centre, which latter sends the mandates along the phrenic and recurrent laryngeal nerves for the purposes mentioned. Now the phrenic is a nerve of considerable length, arising, as usually stated, from the third and fourth and fifth cervical nerves. The group of nuclear cells however from which its force is derived is situated high up in the medulla, near the origin of the vagus and the paramount importance of its function to life is clearly shown in the circumstance that three distinct lines are at first provided for the transmission of the phrenic centre mandates to the great muscle of inspiration. These three lines are separate in the cervical region, where the action of the muscles of that region and the movements of the neck might disturb or interrupt the action of any single line of communication, while they ultimately become fused into one cord in the cavity of the chest, where interrupting influences cannot operate. Such, I believe, may be considered the cause of the mode in which the nerve originates as described. The security of the nerve is further shown in the fact that by piercing the muscle its filaments are distributed on the under surface of the diaphragm, where the weight of the contents of the thoracic cavity could not interfere with the transmission of nerve force. Now the recurrent laryngeal nerves are given off by their respective vags, the right winding round the subclavian artery, the left bending round the arch of the aorta, to reach their destinations in the peculiar lengthened course, for which some special reason must undoubtedly exist. The extraordinary length of these nerves is strikingly exemplified in such animals as the giraffe and the horse. They contain, as is well known, motor filaments for all the muscles of the larynx except the crico-thyroid, which is innervated by the only motor filament found in the superior laryngeal nerve. I shall afterwards refer to this fact in corroboration of the view which I am now seeking to establish. Of these intrinsic laryngeal nerves the crico-arytenoidæ postici by their contraction are alone engaged in opening the rima of the glottis by turning outwards the anterior angle of the arytenoid cartilages and throwing the space between the vocal cords into the shape of a rhomb of considerable size. These muscles, as already stated, are set in action by the long winding inferior laryngeal nerves. Now if it be conceded that the dilatation of the rima and descent of the diaphragm must be simultaneous, it must also be admitted that if the nerves which convey the motor impulses to the crico-arytenoidæ postici passed in a direct course to them, as in the track of the superior laryngeal nerve, the rima would begin to dilate before the diaphragm had commenced to expand the chest and the action of the base and apex of the respiratory cone would not have been synchronous. In a word, the unequal lengths of the supposed direct laryngeal and phrenic nerves would have prevented the occurrence of the synchronous action of the crico-arytenoidæ postici and diaphragm muscles. To remedy this state of things nature has with admirable simplicity rendered the nerves of equal or very nearly equal length by causing the laryngeal nerves to take their circuitous winding course, and in this way, by equalising the length of the phrenic and laryngeal nerves, to equalise the time taken in the transmission of motor impulses from the respiratory centre along their respective nerves to the diaphragm and muscles of the rima, so that when the chest is fully expanded by the complete descent of the diaphragm the rima has reached the largest development and the crico-arytenoidæ postici have contracted to their extreme degree, as expiration proceeds by relaxation of the diaphragm the vocal cords are brought into closer approximation by the crico-arytenoidæ laterales. It is manifest that the diaphragm and these muscles must act synchronously for it would be impossible for respiration to proceed regularly were the rima to open before the diaphragm descended, and still more were the diaphragm to be descending while the rima had not only ceased to open but had actually commenced to contract. If on the other hand, we examine the action of the muscles which are concerned in the production of phonation we observe that the vocal cords are rendered tense by the crico-thyroid muscle pulling the thyroid forwards and downwards on the cricoid cartilage and this tension is obtained

solely by the innervating power of the external branch of the superior laryngeal, the only motor filament contained in that nerve. This is a direct line for transmission of nerve force from the respiratory centre to the larynx. That this tension is of absolute importance to the formation of a laryngeal sound is shown by Louget's experiments. He says 'I have isolated and divided in dogs the nerve branches which exclusively innervate the crico-thyroid muscles and have immediately observed a remarkable hoarseness of the voice due to sudden relaxation of the cords and I have made the hoarseness to disappear by approximating by means of pincers the thyroid and cricoid cartilage.' It is clear that, as a first step in phonation, the vocal cords must be placed on the stretch, their points of insertion must be rendered fast and then, and not till then, can the varieties of note be produced by the various causes which act in affecting the varying tension of the cords. I repeat, the cords must be made fast and tight before they can be made to elicit distinct notes. If this view be granted it is evident that a motor impulse must be communicated to the crico-thyroid before the other laryngeal muscles are set in action. An objection might possibly be offered to this scheme of equalising the times of transmission along the phrenic and inferior laryngeal nerve from an idea that nerve force travels with such rapidity that, like electricity, distance such as a few feet or yards or even inches is not worthy of consideration, that, in fact, an impulse starting from the respiratory centre would reach the laryngeal muscles practically as quickly whether it took the direct course of the superior laryngeal nerve or the winding track of the inferior. Practical physiologists have, however, completely negated this view and have shown that the transmission of nerve force is by no means rapid and that its velocity contrasts wonderfully with the speed of the electric fluid, with which it has been by some writers considered identical. Thus Helmholtz tells us, as the result of his careful experiments, that nerve force travels at the rate of 110 feet per second, and we learn from Wheatstone that the electric fluid speeds with a flight of 283,000 miles per second. Now, if we compare the velocities of the two fluids we find—

$$\begin{array}{rcl} \text{Velocity of electricity} & = & 283,000 \text{ miles} \\ \text{Velocity of nerve force} & = & \frac{110 \text{ feet}}{1,520,640,000 \text{ feet}} \\ & = & \frac{110 \text{ feet}}{155,421,000 \text{ feet}} \end{array}$$

—i.e. the electric fluid travels at a rate nearly fourteen million times quicker than nerve force. In fact, if we remember that, in a man six feet in height, a motor impulse requires nearly one-twentieth of a second to travel from brain to his feet we cannot admit that nerve force possesses a great velocity and we may fairly concede that the lengthening of the inferior laryngeal nerve must also lengthen the time required for the impulse from the respiratory nerve centre to reach the crico-arytenoid muscles which dilate the rima glottidis. Again, the necessity of a synchronous action of the crico-arytenoidæ postici and the diaphragm might be doubted, but it is, I think, clear that these muscles are not in unison the inspiratory and expiratory movements might be conducted in such an irregular manner as to endanger life. Suppose, for instance, the rima commences to open some time after the diaphragm begins to draw air into the chest, a condition of breathing similar to what is found in laryngismus stridulus would ensue and death might result from the imperfect supply of air to the lungs. The importance therefore of a synchronous action of the crico-arytenoidæ postici muscles and the diaphragm is fully shown, and in order to obtain this result the phrenic and inferior laryngeal nerves are made to approximate, if not to equalise, in their lengths respectively and in this way is the circuitous winding course which the inferior laryngeal nerves are compelled to take satisfactorily explained.

BRITISH NURSES' ASSOCIATION — It has been decided to hold a Nursing Congress at Chicago in June next, and Mrs. Bedford Fenwick, 20 Upper Wimpole-street, has been requested to organise the British Section. We are informed that that lady will be prepared to receive papers on subjects connected with nursing written by trained nurses, and will submit them to the organising committee in America. Amongst the papers already promised will be one written by H. R. H. Pinner, Chairman of the Work of the Royal British Nurses' Association and another by Mrs. Bedford Fenwick on Home Hospitals.

TETANY AS A SEQUELA OF PUERPERAL ECLAMPSIA

By S. W. WHEATON, M.D., M.R.C.P. LOND., D.P.H.,
PHYSICIAN TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN
WATERLOO ROAD S.E.

MRS. M—, aged twenty, primipara, was confined at 10.45 A.M. on March 2nd, 1890. The labour was not unduly prolonged, the presentation was of the vertex, the child (a male) was living and there was no undue loss of blood. Before labour the patient was noticed to be pale and complained of pain in the loins, but as there was no cedema anywhere the urine was not examined. Immediately after the expulsion of the placenta at 11 A.M. she was seized with convulsions. When I saw her for the first time at 3.15 P.M. thirteen attacks of general convulsions had occurred and she was lying in a comatose condition, with dilated pupils. The conjunctival reflex was absent, respiration was rapid and irregular and crepitations were heard at the bases of both lungs, the temperature was 100°, the pulse was 150, very feeble but incompressible. The secretion of urine was very scanty, a few drachms drawn off by catheter were solid with albumen and contained blood, blood casts, and only $\frac{1}{2}$ per cent. of urea on subsequent analysis. I at once applied wet cupping to both loins and removed half a pint of blood in this way. An eighth of a grain of hydrochlorate of pilocarpin was injected subcutaneously, and twenty grains of chloral and one drachm of bromide of potassium were given per rectum. At 3.45 P.M. another convulsion of a typical epileptic character occurred, preceded by a sighing sound, and, what was particularly noticeable, by marked contraction of the uterus, which could be felt to project forward and become hard under the hand placed upon the abdomen. At 4 P.M. wet cupping and the pilocarpin injection were repeated, from this time improvement commenced and profuse diaphoresis occurred. The next fit did not occur until 5.15 P.M., after which only three fits occurred until the next morning (March 3rd) at 4 A.M., when two occurred within a short time of one another. From this time they ceased altogether. At 10 A.M. she was still unconscious, but could swallow, the conjunctival reflex had returned and the temperature had risen to 103°. Dr. W. O. Priestley kindly saw her for me, and recommended liquor ammoniac acetatis (two drachms every two hours), which was given, as also were a purge and enema. Flurty ounces of urine were collected during the twenty-four hours of this day, containing 4 per cent. of urea and $\frac{1}{2}$ per cent. of albumen. The next day (March 4th) the patient continued unconscious and the temperature was continuously high at 102° to 103°. There were no signs of lung mischief, but a systolic murmur appeared at the apex of the heart and also at the left base, but without increase of dulness in the cardiac area. Thirty-nine ounces of urine were drawn off—March 5th. This morning, while still unconscious, she was noticed by the nurse to have spasmodic attacks of rigidity of the limbs. When seen two hours later she was lying on her back with the arms rigidly extended by her sides, the hands semiflexed at the wrist, the proximal joints of the fingers of both hands flexed and the two distal joints extended, the fingers were approximated and adducted as a whole and the thumbs were rigidly flexed into the palms. The legs were rigidly straightened out, the ankle joints were extended and the toes were adducted. The jaws were rigid, but not so much as to prevent the giving of food. Pressure on the limbs caused increased rigidity. This condition, which was thus typical of tetany, lasted for three days, at the end of which time it gradually disappeared, consciousness also returning slowly. The temperature, which had continued at 102° to 103°, became normal, and the urine increased in quantity to fifty-two ounces. There was complete loss of memory regarding the events preceding the fits, and for some time the patient would not believe that she had been confined. Secretion of milk was entirely absent, but the involution of the uterus proceeded normally. In three weeks convalescence was complete, there was only a trace of albumen in the urine and the cardiac murmurs had disappeared. Six months later the urine contained a trace of albumen. I have seen her twice since the last time three months ago and on each occasion albumen has been absent from the urine and there were no signs of increased arterial tension. She has not become pregnant again.

Tetany always occurs after some cause producing ex-

haustion or defective nutrition of the nervous system. Especially is this the case in the easily exhausted nervous system of children, in whom tetany is so common as the so-called "carpo pedal contractions." These contractions may follow convulsions, diarrhoea, teething or any exhausting cause. In adults tetany principally occurs in women, especially from the exhaustion of lactation or pregnancy under unhealthy surroundings, and also in connexion with hysteria as in a case reported by Dr. Gaiger.¹ Tetany may be regarded as the result of profound exhaustion or malnutrition of the higher motor centres of the cerebral cortex, in consequence of which the restraining influence is withdrawn from a lower stratum of cells, which are thus allowed to come into action without any regulation from higher centres. The normal action of this lower stratum of cells is to initiate movements corresponding to the typical attitudes of this disease, consequently when the higher control is withdrawn their uncontrolled action produces permanent contractures. In the case in point the exhaustion of the higher centres was due to the repeated convulsions, and its intensity was marked by the long period of unconsciousness and absence of voluntary movement, also by the persistent high temperature, which latter is also probably due to the unregulated action of lower heat-producing centres, owing to the exhaustion of higher controlling ones. That no organic lesions exist in tetany is proved by the fact that it may recur in the same subject again and again at intervals. The cardiac murmurs were undoubtedly due to anaemia, although at the time they gave rise to a suspicion of ulcerative endocarditis. This is frequently seen as the result of septicæmia after delivery, to which cases of eclampsia are particularly exposed owing to the failure of antiseptics in patients with convulsions and suffering from involuntary evacuations. Another point of interest is the increase in the amount of urine and urea which followed measures for the relief of kidney congestion. No treatment was ordered for the tetany except quinine and iron, it is essentially a symptom of defficientation of the nervous centres and requires a tonic treatment. Dr. Dakin has collected eight cases of tetany during pregnancy², they all occurred before delivery—not after, as in the present case—and one ended fatally.

Clapham-common, S.W.

A CASE OF TRAUMATIC ANEURYSM OF THE POPLITEAL ARTERY

LIGATURE OF ARTERY ABOVE AND BELOW THE WOUND,
FOLLOWED BY GANGRENE AND SECONDARY HÆMOR-
RHAGE, AMPUTATION, RECOVERY

By BRIGADE-SURGEON LIEUTENANT COLONEL
O. E. HARRISON, M.B. LOND., F.R.C.S. ENG.,
GRENADEIR GUARDS

A CORPORAL in the Grenadier Guards was admitted to the Guards Hospital on the evening of October 6th, 1890, with a small punctured wound in the upper third of the calf of the left leg. He stated that in climbing over some iron railings the pointed end of one of the railings had wounded the leg, that he had lost a good deal of blood at the time, and that an officer's servant, who was close by, assisted him into a cab and brought him to the hospital at once. On admission there was little or no bleeding, and on careful examination no evidence could be found that any large vessel was injured. The wound was dressed with carbolic lotion, and the man was ordered to remain in bed. Everything appeared to progress favourably until the 13th, when he stated that in the early morning he had felt his leg uncomfortable. On examining the leg distinct pulsation could be felt and seen over a small area immediately above the level of the wound. There was a little resistance to pressure with the fingers here but there was no marked swelling. The pulsation was completely controlled by pressure on the femoral artery at the groin. The man's urine was found to be free from albumen, but a marked hardness was observed in the radial arteries which could be traced far up the forearms. The opinion was formed that a small traumatic aneurysm existed and the limited

¹ THE LANCET Aug 20th 1887

² Obstetrical Society's Transactions vol xxxi p 163.

area and superficial character of the pulsation led to the hope that one of the muscular branches to the gastrocnemius had been wounded rather than the main artery of the limb. It was determined to make an exploratory incision with a view to tying the wounded vessel. A tourniquet having been placed over the femoral artery and an elastic bandage tied firmly round the limb above and below the knee, a probe was carefully introduced into the wound. No reliable information could be obtained by the probe as to the original course of the wound, but it passed rather deeply in an upward direction towards the centre of the popliteal space. An incision, which was subsequently enlarged so as to extend from four inches and a half to five inches, was made from the wound directly over the area of pulsation. The fascia having been divided, the fibres of the head of the gastrocnemius were carefully cut through and the popliteal vein exposed. The tourniquet and elastic bandages having been loosened, the condition of the artery was carefully examined with the finger—without separating it from the vein—both above the level of the gastrocnemius and where covered by the head of that muscle. No extravasated blood was seen, no hemorrhage occurred except a very trifling amount from the vessels divided at the time of the operation, and no abnormal condition of the main artery or its branches could be detected. It was not thought advisable to carry the dissection farther. A drainage-tube was placed in the lower angle of the wound, which was washed out with a weak solution of perchloride of mercury and closed with silver wire and silk sutures. Anti-septic dressings were applied and the knee was slightly flexed and placed on a splint. The temperature at night was normal. A morphia draught was given. On the following day (14th) the temperature was 99 in the morning and evening with a pulse of 84 and 88 respectively. On the 15th the wound was dressed and was looking healthy. There was a little oedema about the ankle and leg. The pulsation was found to be quite as marked as before the exploratory operation. In the evening Mr Howard Marsh kindly saw the patient. He did not consider it possible at that time to express a decided opinion as to the exact injury, but thought the evidence pointed to the wounding of an artery at the time of the accident or to a strain or bruising of the coats of the artery which had subsequently given way. He recommended that pressure should be applied to the femoral artery and the condition of the leg watched. The morning temperature was 99 and pulse 79. The evening temperature was normal. On the 16th the leg had been uneasy and a morphia draught had not secured a good night's rest. The wound looked healthy but there was more swelling on the inner and anterior aspect of the leg. Pulsation could be felt over a rather wider area. There was some discolouration—as from bruising—even as low as the ankle. The temperature was normal, the pulse 67. In the afternoon pressure was applied over the femoral artery by means of the fingers aided by a sandbag suspended by a cord passed over a pulley screwed into a beam in the ceiling, and this was varied by pressure applied by means of a Skey's tourniquet. The evening temperature was normal and the pulse 64. On the 18th the oedema was slowly decreasing but not so the pulsation. A thrill could be felt just on the outer side of the incision and a double bruit heard on auscultation over the area of pulsation. There was some increase of swelling on the inner surface of the calf in its upper part and pulsation was now felt here, and markedly so over the line of the incision. The evening temperature was raised one degree. The pressure was omitted during some part of the night. On the 21st the oedema of the limb was less. The pressure had been omitted during the last three nights but had been continued during the daytime. On the 23rd a continuous thrill, occupying the dilatation and subsidence of the arterial pulse, could be felt on lightly touching the skin over a limited area just to the outer side of the scar left by the incision. Pulsation was marked over the centre of the scar, and could be felt less distinctly up to the posterior border of the tibia on the inner side of the calf. A loud, prolonged, almost continuous musical bruit was audible over the area of pulsation. Pressure had been omitted on the 21st, but resumed after midday on the 22nd. Mr Marsh again kindly saw the patient and it was determined to try the effect of pressure applied to the limb by means of a perforated Martin's bandage, the foot being kept well raised. It was thought that the local signs indicated the presence of a varicose aneurysm of the posterior tibial or of the popliteal artery just before its division. On the 30th little or no change in the condition of the leg had taken place except that the oedema of the limb had been

reduced by the bandage. The temperature and pulse were favourable. On Nov 3rd the aneurysm appeared fuller and tenser. On the 7th it was felt that some operative interference should be resorted to in order to prevent the risk of rupture of the aneurysm and consequent extravasation into the limb. The aneurysm felt tenser, and the area of pulsation was slowly extending. Mr Marsh kindly came to the hospital and gave his valuable assistance and advice in the operation. The limb having been raised and an Esmarch's round elastic bandage applied just below the centre of the thigh, an incision was made commencing a little to the inner side of the middle of the popliteal space and continued downwards over the gastrocnemius for about five inches. After carefully cutting through the gastrocnemius and ligaturing those branches of the sural arteries which were divided, a very thin walled sac was exposed evidently the sac of the aneurysm. It was thought advisable to expose and ligature the artery above and below the sac. The incision having been extended a little upwards, the tissues were dissected through until the popliteal artery was exposed above the upper boundary of the sac, about the level of the centre of the popliteal space. A double ligature of silk thread which had previously been boiled in carbolic solution, was applied and the artery cut through between the two ligatures. The dissection was then continued over the lower end of the sac, the cutaneous incision being extended to the centre of the calf. The upper border of the soleus muscle was exposed, forming the lower boundary of the aneurysmal sac. The fibres of the soleus just below its origin were therefore carefully divided until the posterior tibial nerve was exposed, when the posterior tibial artery was readily found and ligatured. The aneurysmal sac was then incised and opened up nearly to its full extent with scissors. It was then seen that the popliteal vessels had been pushed towards the outer side of the limb by the aneurysm and, after the blood and blood clot had mostly been removed a round opening, the size of a millet seed, was found on the inner side of the popliteal artery, communicating directly with the sac of the aneurysm about the centre of its outer side. The artery was ligatured above and below this opening in its walls. The aneurysm had extended deeply in the direction of the interosseous membrane as well as towards the surface of the calf. The Esmarch's bandage having been loosened, the bleeding points were secured. Some dense portions of the clot which were adherent rather firmly to the sac were left *in situ*. There was a little oozing from the upper extremity of the sac which it was found difficult to arrest. The wound and interior of the sac were sponged out with perchloride of mercury solution, a drainage-tube was inserted into the lower angle of the wound and the part dusted over with iodoform. The wound which was about nine inches long, was closed with silver wire sutures, and lint moistened with perchloride of mercury solution was applied to the surface. A piece of protective was placed over this and iodoform wool added to cover the whole. A poroplastic back splint was placed behind the knee and the limb enveloped in cotton wool. The patient was very chilled after the operation. Hot water bottles were placed in the bed. In the evening the temperature was 101.2° and pulse 120. He felt fairly comfortable. The toes of the left foot were cold, there was some slight degree of warmth on the upper surface of the foot. On the 8th the temperature was 102.8°, the pulse 128. He had passed a restless night in consequence of pain of a burning character in the calf and in the toes which opium had not relieved. The evening temperature was 104.2° and the pulse 150. The next day the wound was dressed. There had been considerable oozing of blood stained fluid into the dressings. There was a little fulness to the inner side of the lower part of the wound, which was otherwise looking well. The drainage-tube was syringed out with perchloride solution and the wound dressed as before. There was staining of the front of the foot and lower part of the front of the leg from extravasation of blood into the superficial part of the skin. The temperature was 103.6°, the pulse 139. The man's aspect was good, and he had passed a fair night. The evening temperature was 104.2°, and the pulse 141. On the 10th some blood stained fluid had during the night soaked through the lower part of the dressings, and on dressing the wound a gangrenous odour was very marked. The upper part of the foot was rather dusky and mottled—the toes were chilly and the dorsum of the foot and leg were warm. A large bulla—containing dark, blood stained fluid—had formed over a considerable area of the lower and inner part of the left leg. The leg up to the knee was infiltrated

TETANY AS A SEQUELA OF PUERPERAL ECLAMPSIA

At 4 P.M. wet cupping and the pilocarpin injection were repeated, from this time improvement commenced and profuse diaphoresis occurred. The next fit did not occur until 5 15 P.M., after which only three fits occurred until the next morning (March 3rd) at 4 A.M., when two occurred within a short time of one another. From this time they ceased altogether. At 10 A.M. she was still unconscious, but could swallow, the conjunctival reflex had returned and the temperature had risen to 103°. Dr W O Priestley kindly saw her for me and recommended liquor ammoniac acetatis (two drachms every two hours), which was given, as also were a purge and enema. Thirty ounces of urine were collected during the twenty-four hours of this day, containing 4 per cent of urea and $\frac{1}{2}$ per cent of albumen. The next day (March 4th) the patient continued unconscious and the temperature was continuously high at 102° to 103°. There were no signs of lung mischief but a systolic murmur appeared at the apex of the heart and also at the left base, but without increase of dullness in the cardiac area. Thirty-nine ounces of urine were drawn off.—March 5th. This morning, while still unconscious, she was noticed by the nurse to have spasmodic attacks of rigidity of the limbs. When seen two hours later she was lying on her back with the arms rigidly extended by her sides, the hands semiflexed at the wrist, the proximal joints of the fingers of both hands flexed and the two distal joints extended, the fingers were approximated and adducted as a whole and the thumbs were rigidly flexed into the palms. The legs were rigidly straightened out, the ankle joints were extended and the toes were adducted. The jaws were rigid, but not so much as to prevent the giving of food. Pressure on the limbs caused increased rigidity. This condition, which was thus typical of tetany, lasted for three days, at the end of which time it gradually disappeared, consciousness also returning slowly. The temperature, which had continued at 102° to 103°, became normal, and the urine increased in quantity to fifty-two ounces. There was complete loss of memory regarding the events preceding the fits, and for some time the patient would not believe that she had been confined. Secretion of milk was entirely absent but the involution of the uterus proceeded normally. In three weeks convalescence was complete there was only a trace of albumen in the urine and the cardiac murmurs had disappeared. Six months later the urine contained a trace of albumen. I have seen her twice since, the last time three months ago and on each occasion albumen has been absent from the urine and there were no signs of increased arterial tension. She has not become pregnant again.

Tetany always occurs after some cause producing ex-

haustion or defective nutrition of the nervous system. Especially is this the case in the easily exhausted nervous system of children, in whom tetany is so common as the so called "carpo pedal contractions". These contractions may follow convulsions, diarrhoea, teething or any exhausting cause. In adults tetany principally occurs in women, especially from the exhaustion of lactation or pregnancy under unhealthy surroundings, and also in connexion with hysteria as in a case reported by Dr Criger.¹ Tetany may be regarded as the result of profound exhaustion or malnutrition of the higher motor centres of the cerebral cortex, in consequence of which the restraining influence is withdrawn from a lower stratum of cells, which are thus allowed to come into action without any regulation from higher centres. The normal action of this lower stratum of cells is to initiate movements corresponding to the typical attitudes of this disease, consequently when the higher control is withdrawn their uncontrolled action produces permanent contractures. In the case in point the exhaustion of the higher centres was due to the repeated convulsions, and its intensity was marked by the long period of unconsciousness and absence of voluntary movement, also by the persistent high temperature, which latter is also probably due to the unregulated action of lower heat-producing centres, owing to the exhaustion of higher controlling ones. That no organic lesions exist in tetany is proved by the fact that it may recur in the same subject again and again at intervals. The cardiac murmurs were undoubtedly due to anaemia, although at the time they gave rise to a suspicion of ulcerative endocarditis. This is frequently seen as the result of septicæmia after delivery, to which cases of eclampsia are particularly exposed owing to the failure of antiseptics in patients with convulsions and suffering from involuntary evacuations. Another point of interest is the increase in the amount of urine and urea which followed measures for the relief of kidney congestion. No treatment was ordered for the tetany except quinine and iron, it is essentially a symptom of deficient action of the nervous centres and requires a tonic treatment. Dr Dakin has collected eight cases of tetany during pregnancy², they all occurred before delivery—not after, as in the present case—and one ended fatally.

A CASE OF TRAUMATIC ANEURYSM OF THE POPLITEAL ARTERY

LIGATURE OF ARTERY ABOVE AND BELOW THE WOUND,
FOLLOWED BY GANGRENE AND SECONDARY HÆMO-
RHAGE, AMPUTATION, RECOVERY

By BRIGADE-SURGEON LIEUTENANT COLONEL
C E HARRISON, M B LOND, F R C S ENG,
GRENADIER GUARDS

A CORPORAL in the Grenadier Guards was admitted to the Guards Hospital on the evening of October 6th, 1890, with a small punctured wound in the upper third of the calf of the left leg. He stated that in climbing over some iron railings the pointed end of one of the railings had wounded the leg, that he had lost a good deal of blood at the time, and that an officer's servant, who was close by, assisted him into a cab and brought him to the hospital at once. On admission there was little or no bleeding, and on careful examination no evidence could be found that any large vessel was injured. The wound was dressed with carbolic lotion, and the man was ordered to remain in bed. Everything appeared to progress favourably until the 13th when he stated that in the early morning he had felt his leg uncomfortable. On examining the leg distinct pulsation could be felt and seen over a small area immediately above the level of the wound. There was a little resistance to pressure with the fingers here, but there was no marked swelling. The pulsation was completely controlled by pressure on the femoral artery at the groin. The man's urine was found to be free from albumen, but a marked hardness was observed in the radial arteries which could be traced far up the forearms. The opinion was formed that a small traumatic aneurysm existed and the limited

with oedema, and in places there was a blush on the surface of the skin. A dirty, foul smelling discharge had come from the wound. The temperature was 103.6° and the pulse 125. The advisability of amputating the limb above the knee was discussed, but, although the man's aspect was good, it was considered that the temperature and pulse were not favourable for immediate amputation. Mr. Marsh kindly saw the man and recommended that some of the sutures should be removed, the wound freely irrigated and the limb put up in boracic poultices covered with protective and wool. On the 12th the temperature was 101.4°, the pulse 113. There was less redness of the leg below the wound, which was in a sloughy condition. The wound was irrigated three times during the day with carbolic lotion (1 in 80) with a little tincture of iodine. The patient was taking food very fairly, with four ounces of brandy, and two grains of quinine three times a day. The evening temperature was 103.2° and the pulse 114. The opium was continued at night. On the 16th the temperature had fallen to 98.7° and the pulse to 96. The evening temperature was 100.8° and the pulse 104. On the 17th the wound was looking healthier, but there was a large patch of gangrenous skin and subcutaneous tissue extending over nearly the lower half of the inner side of the leg, and passing round the back and a portion of the outer side. The toes were becoming mummified, and the condition of the foot gave rise to anxiety. The superficial parts on the inner side of the heel were dead, and there was some duskeness with oedema of the dorsum with little or no sensation from just below the ankle in front. The irrigation was continued, a charcoal poultice applied to the lower part of the leg and the brandy increased to six ounces. On the 20th the temperature was 99.6° and the pulse 98. A considerable portion of the soft tissues of the leg and foot was evidently dead, including the greater part of the gastrocnemius and soleus. Mr. Marsh saw the patient, and it was decided to wait and watch from day to day in the hope that the structures of the upper part of the leg would sufficiently recover to justify amputation below the knee. In the event of secondary hæmorrhage occurring it was decided that the limb should be amputated at once. On the 21st secondary hæmorrhage occurred at midday from a point deeply situated in the upper angle of the wound, this being the fifteenth day since the ligatures were applied. The femoral artery was compressed with the fingers and preparation made at once to amputate above the knee. Chloroform having been administered, the limb was removed, anterior and posterior skin flaps being made with circular incision through the muscles. Surgeon Major Magill, Coldstream Guards, kindly assisted me. A very marked collapse followed, but the patient rallied satisfactorily. The cut surface of the stump was freely washed with perchloride of mercury solution and dressed with strips of gauze moistened with this solution, iodoform having been previously dusted over the skin and edges of the flaps. Catgut ligatures were used and the stump enveloped in sal alembroth wool.

On examining the leg which had been amputated the site from which the hæmorrhage had come appeared to be the point at which the highest ligature had been placed on the popliteal artery. The ligature was almost completely detached and the proximal end of the artery on its inner side looked eroded. There was no evidence of organised clot in this part of the artery. The superior external articular artery was given off a little above this level. The ligature on the popliteal artery immediately below the point where the artery had been cut through after being ligatured was still firmly attached. The walls of the artery in contact with what had been the sac of the aneurysm were partially disorganised. The ligature on the posterior tibial artery was still firmly attached, with a clot above and below. The anterior tibial artery was given off a short distance above this ligature. All the muscles on the back of the leg below the lines of demarcation were in a state of gangrene and in the lower part of the leg the bones were denuded of periosteum. The muscles of the sole of the foot were gangrenous and the tissues on the dorsum were becoming so. The patient made a rather slow but a very satisfactory recovery, and was eventually discharged from the service on July 3rd, 1891, with a very useful stump and wearing an artificial limb.

Remarks.—The nature and rarity of the accident in this case render it one of considerable interest. Anxiety as to the best method of treating the case was occasioned by the fact that the physical signs and symptoms left great doubt as to whether the artery alone was wounded or whether a wound of both the artery and the vein had led to a communication between those vessels and the formation of a

varicose aneurysm. Under these circumstances it was determined to try the effect of pressure, and, if this failed, to cut down upon the vessels at the seat of injury rather than to apply a ligature higher up. A case in which the symptoms were almost identical with those in the present instance, and in which Mr. Thomas Smith was successful in effecting a cure by means of pressure applied to the limb by a Martin's bandage, led me to hope that a similar good result would be attained in this case. A cure, however, by these means was not attained. The occurrence of sepsis, notwithstanding the care which was taken to prevent this result, must probably be explained by the extent and nature of the wound, which rendered aseptic treatment difficult under the circumstances. The published cases of traumatic aneurysm of the popliteal artery appear to be few in number.

Rechester row, S.W.

A CASE OF INFLUENZA WITH INTERESTING SEQUELÆ

By LOUIS E. STEVENSON, M.B., B.C. Cantab.,
LATE HOUSE SURGEON TO THE CUMBERLAND INFIRMARY, CARLISLE.

THIS case occurred in the practice of my friend, Dr. Stewart Lockie of Carlisle, and to him I am indebted for the following notes. The case had a fatal termination, and at Dr. Lockie's request I conducted the necropsy with him.

A housekeeper aged fifty-seven first came under Dr. Lockie's care on Jan. 25th, 1890. Before this date her health had been impaired for some months and she particularly suffered from occasional abdominal pain. On Jan. 13th she was seized with a mild attack of influenza, then epidemic in the city. She was convalescent from this and was doing fairly well, but on Jan. 24th she was attacked with severe pain in the abdomen, referred to the hypochondriac, umbilical and epigastric regions. When Dr. Lockie saw her on the 25th the abdomen was soft, there was a degree of tenderness on pressure, the abdominal muscles moved on respiration, and the pain was not increased on coughing, there was no vomiting, the bowels had been regular, pulse-rate and temperature were normal. A mixture containing sulphate of magnesia and Dover's powder was ordered. On the 27th there had been some vomiting, the bowels had been moved repeatedly and the stools were loose. The pain was unrelieved and had extended low down in the umbilical region and to both lumbar regions. Tenderness was present, but no tumidity. The abdominal muscles still moved on respiration. On the 28th there was less pain, but on the following day it became much worse and there was some tumidity. There was abdominal tenderness, especially in the right lumbar region, vomiting had ceased. Opium, which had been given at the beginning, was now freely administered with some relief. On the 30th and 31st the patient was easier, but the temperature rose to 100° and the pulse had quickened. Tenderness was now most marked in the left iliac region. In the evening of the 31st it was noticed that the pulse in the right wrist was much more feeble than in the left, only some beats could be felt in the former, whilst in the latter there was a fair regular pulse of 120. The patient said that for two days the right arm had been slightly numb. At midnight the arm became very painful, cold and apparently bloodless as far as the elbow. At 3 A.M. on Feb. 1st no pulse could be felt in the right superior extremity below the axilla, the forearm and hand were cold and somewhat shrivelled, and the hand livid, sensibility was abolished below a line one inch above the wrist. Opium was still more freely administered, and with relief. At this time the pain in the abdomen was less and the tenderness was confined to the left iliac region. There was regurgitation from the stomach, but no actual vomiting. Later on the same day a copious loose stool was passed in which were some specks of blood and shreds of mucus. On the morning of the 2nd the condition was practically unchanged, but the pulse had disappeared in the axilla. On this day the patient had another copious loose evacuation, but it contained no blood. On the evening of the 2nd a great change for the worse took place. The face was pinched, the extremities were cold, respiration laboured and the pulse had risen to 144 being very feeble. Death took place on the 3rd, at 1.30 P.M.

The necropsy, which was conducted on the 4th, revealed the following interesting pathological conditions. The abdominal cavity contained a small quantity of black, blood stained fluid,

pneumothorax we cannot expect relief in cases in which the increasing pressure within the chest is not greater than that of the atmosphere. This statement is also borne out in the reports of Dr. Sutherland of the North London Hospital for Consumption. Where tuberculous matter becomes deposited on the parietal pleural surface agglutination may take place between it and the pulmonary surface, with the result that the adhesion between the visceral and the costal layers may save the tuberculous patient from a pneumothorax. This *vis medicatrix nature* is often exerted, and in a like manner a pneumothorax once formed may retard the phthisical process by giving rest to the diseased lung through compression. In such a case the therapeutic effect of the pneumothorax may be effective in benefiting the phthisical patient for a short period. It might be supposed that individuals whose lungs are greatly reduced by the subsequent contraction of the chest would necessarily be reduced to a frail state of health and low scale of bodily strength, yet, curiously enough, some persons can follow the active pursuits of life, as instanced in Case 1. Laennec mentions the case of a distinguished Paris surgeon who, although he had one side contracted in a marked degree from empyema, yet enjoyed the best of health and lectured to his students twice daily. A similar case came under my observation in Bedfordshire, the subject of which is now getting his living as a flautist.

Shakespeare-villas, Nottingham.

REPORT ON

AN OUTBREAK OF ENTERIC FEVER IN
WARDS 3, 4 AND 5 OF THE BOROUGH
OF LEICESTER

By J. PRIESTLEY, B.A. LOND., M.D. EDIN., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH AND PUBLIC ANALYST
BOROUGH OF LEICESTER.

FROM January to April of last year there were two cases of enteric fever notified as having occurred in Wards 3, 4 and 5 of the Borough of Leicester. Since then twenty cases have been reported—viz., three in May, four in June, five in July, five in August and three in September. All these I have succeeded in tracing directly or indirectly to the consumption of herb beer infected, in my opinion, with enteric fever contagium.

The first case was that of F. M., in B— street, a fire-roomed house. He was notified as suffering from enteric fever on May 7th, and on investigation it was found that he had been ill for eleven days. The child was lying on an improvised bed in a back room, where he had lain for that time, the front room being used as a shop, where provisions, herb beer &c. were sold. The back room was in use as a living room for the whole family, consisting of Mr. and Mrs. M., seven children and the grandfather. At the time of the inspector's visit Mrs. M. was engaged in brewing the herb beer in the room where the child suffering from enteric fever was lying. A punchbowl containing a few gallons of herb beer was standing in the room without a cover and in the act of being fermented with yeast. An iron pot containing boiling herbs was on the fire. The mother was cautioned by the inspector as to the danger she was incurring by brewing herb beer in a room in which a fever patient was lying, and the child was some days afterwards (May 20th) removed to the infirmary, but no further action was taken, as this was the time during which there was no medical officer of health in Leicester, my predecessor having died.

Since this case nineteen others suffering from enteric fever have been notified, and on making strict inquiries and close investigations as to drainage defects and milk and water supplies at the houses in which the cases occurred, I was satisfied that the facts that were brought out were not sufficient to account for all the cases, or even for the majority. I was accordingly led to look further, and a fact that attracted my attention was the 'good trade' that was being done in the sale of herb beer from the very shop in the back room of which the child (F. M.) had been found by the inspector to be suffering from enteric fever and where the herb beer was actually made. Starting from B— street as a centre I succeeded in tracing the herb beer definitely to nine and indefinitely to six of the houses where enteric

fever had been notified as having occurred. In only five out of the twenty cases was I unable to get a history of herb beer having been drunk. I may explain that in using the word "definitely" I mean the history was distinct and the case proved conclusively—e.g., "gift" tickets given away to purchasers of the herb beer were shown &c., whereas in those cases I have described as "indefinitely" traced, I mean that the evidence of herb beer drinking was distinct, but it could not be traced to B— street. Considering, however, that the houses were in the neighbourhood and that young people are apt to spend their pennies without being able to tell exactly a little while after where they spent them, we may reasonably suppose that some of the indefinite cases may also have partaken of the infected beer. Then, again, I was able to trace the fact that one other shop dealing in herb beer had on emergency replenished its supply temporarily from B— street, so that we may conclude that of the twenty cases fifteen had a history more or less definite of having partaken of the infected beer. I am by no means satisfied in my own mind that the remaining five cases had not also partaken of it, but from a statistical standpoint I am sorry I have been unable to prove this conclusively.

I may mention here that several cases of illness which the medical men in attendance have not felt justified in notifying as enteric fever but which they have admitted were of a distinctly enteric type have come to my knowledge. The important bearing of this must be evident when I say that I myself, as medical officer of health without private practice, have seen ten such cases lately.

An interesting though tragic episode in the epidemic deserves mention. On Aug. 8th Mr. M. (the mother) who brewed the herb beer was notified as suffering from enteric fever. She had been ailing off and on for fourteen days previously, and on July 25th she, with her husband and family removed to M— street, taking with them six bottles of herb beer which they had in stock from B— street. Mrs. M. was finally removed to the infirmary on Aug. 12th and died there on the 27th. I have succeeded in tracing the six stock bottles that were taken from B— street to M— street, two of them having been sold to a Mrs. B., who at present is in good health, and the other four having been drunk by the M.'s themselves, of whom another has since been notified as suffering from enteric fever (Aug. 26th). Indeed, of the M. family mentioned above the grandfather has alone escaped, while four have had enteric fever (one dying) and the remaining five have suffered more or less from pseudo-enteric symptoms—e.g., purging, low fever, depression &c. The grandfather's escape is explicable by his age.

The ill-fated house in B— street was left by the M.'s on July 25th and taken on the same day by a family named B.— who have brewed and sold other herb beer since. There is no illness in the house now, and the M.'s' stock has been removed, not a single bottle remaining in B— street.

With a child lying ill [of enteric fever] in a room where the mother was brewing herb beer it is not very difficult to understand how the mother's hands may have conveyed the germs from the patient into the beer. I need not, I think, however, go so far as this. It is sufficient for my purpose to know that the herb beer when brewed stood uncovered for hours in a room in which a child was lying ill of enteric fever, with a chamber utensil (probably containing typhoid stools) on the ground.

The medical histories of the cases are very definite. Taking the first case in B— street as the infecting centre, and remembering that the child was lying ill in the back room from about May 1st until the 20th—when he was removed to the infirmary—we can understand how the beer brewed during that period was contaminated.

Though the sewage of this particular area is not perfect, there is nothing specially calling for remark, whilst other areas of the town (where the sewerage is worse) show a clean bill as regards enteric fever. Then, again, all the houses affected do not drain into one separate system and the sanitary arrangements are all external. The sinks in all cases were disconnected from the main drainage. All the houses were supplied with the Corporation water, which at that time was good.

Inquiry into the milk supply of the various houses infected gave negative results, though it is a strange coincidence that one particular milkman supplied nine out of the twenty cases. Careful investigations in this direction however showed nothing amiss. I was thus driven to look elsewhere, and I

the fourth interspace, heart in mid sternal line, no epigastric pulsation. Temperature 99°, respiration 18, pulse 80—19th Patient is improving, it was hoped that the withdrawal of the greater quantity of fluid would tend to complete absorption by relieving the overstrained lymphatics—20th The symptoms are the same as yesterday 21st Fluid had reaccumulated and cardiac impulse was again seen in para sternal line, and the symptoms were those of the 17th inst save that the temperature to day was 103°, respiration 28, pulse 100 She had a severe rigor in the night and has been sweating this morning, the sweating being colliquative in character. An egophonic sound is heard at the angle of the left scapula, this sound may be more correctly described as being markedly nasal and continuous, instead of bleating, depending probably upon the interception (by exudation) of the fundamental vowel tone and the passage of harmonic overtones—22nd Cardiac asthenia present. Paracentesis thoracis resorted to and 40 oz. of fluid (turbid) slowly withdrawn, after which the patient improved until the 25th inst., when the following notes were taken. "Improved on the whole, but still complains of pain in the left side, which is now quite immovable. Temperature 101°, pulse 80, respiration 20 Percussion note dull below the third rib, tactile fremitus obtained only above its upper border. Below these points breathing is distinctly amphoric. Heart still displaced"—26th Left side seems much more enlarged and rounded than hitherto and movements are absent. Bell sound is plainly elicited. Dulness extending from the lower border of the third rib is distinctly movable, this is seen if she turns on her back or right side, the percussion note in the axilla being hyper resonant.—27th To day, from the third to the sixth interspace in the mid axillary line, a distinct pulsation or heaving is noticed, the thoracic parietes receiving a marked impulse, synchronous with the ictus cordis, and also systolic in time with the cardiac impulse, which is now defined in the fourth right interspace external to the junction of the cartilages with the sternum. The hand when placed on the side is forcibly lifted at each pulsation.—28th Patient lies in the left lateral decubitus, and in this position the impulse of the heart can be felt in the fourth right space, the pulsations in the left mammary region being plainer to day. Bell sounds very distinct. Succussion absent.—29th Signs similar. Systolic impulse on the left side can be seen at the other end of the room ten feet away. Resonant note is obtained to the upper border of the third rib, from the third to the fifth it is tympanitic and below this point dull. Temperature 101°, pulse 80, respiration 20. Distinct amphoric breathing under the axilla. A needle was introduced and a few drops of pus withdrawn, after which ten ounces of pus were removed from below the inferior angle of the left scapula and a drainage-tube inserted—30th 31st The patient is improving. Temperature 99°—June 1st, 2nd Flattening has taken place in the interspaces and the note is tympanitic from the fourth to the seventh. The patient expresses herself as feeling better than she has all along—4th The discharge is very slight, tube removed, a No 2 (catheter size) introduced. Temperature, pulse and respiration normal. Normal breath sounds over the right lung—7th There being no discharge, the drainage-tube was withdrawn—30th Sinus has healed. Relatives state that the patient looks better than she did before the accident occurred. The chest is still much flattened, the heart now beats to the left of the sternum, but the impulse and first sound are felt and heard in a line one and a quarter inches to the right of the left nipple.

The patient was seen in a month after I discharged her. The notes made were that "although there was considerable flattening of the left parietes there were loud and breezy sounds heard down to the fourth interspace, below this they were somewhat feeble."

Remarks—The special features in this case are the patient's descriptive account of her sensation of something having given way, the remarkably rapid and copious effusion and the intense agony on palpation or even application of stethoscope. From these special features I am led to believe that it was a pneumothorax from the first and that it is one of those interesting cases recorded in the Clinical Society's Transactions by Drs West, De Havilland Hall and Osler. A pneumothorax cannot always be diagnosed at first, for it is well known that the percussion note may be dull when the tension of the thoracic wall is too great, such as it may have been in this case, and, on the other hand, there must be a certain degree of tension in the walls of the cavity to make them good reflecting surfaces, and if this tension be deficient at the spot of the cavity opposite the place where the stethoscope is applied

the tinkling sounds may be absorbed and not reflected. Careful studies of pulsating pleurisies were first recorded in 1844 by Dr Macdonnell,⁴ Professor of Clinical Medicine in McGill University, Montreal, who at that time was clinical assistant to the renowned Graves and Stokes of the Merth Hospital. Coomby states that of thirteen cases nine died,⁵ and in Kepler's practice out of thirty eight cases seventeen died.⁶ Two groups of cases are recognised—viz., the intra pleural and empyema, in which there is an external pulsating tumour. The latter usually occurs in cases in which the fluid has existed for some time, but that it does occur in acute cases, even with serous exudation, is verified in the cases reported by Dr Osler of Pennsylvania.⁷ Various suggestions for the phenomenon are put forward, one being that it occurs when adhesions exist between the layers of the pericardium and between the latter and the chest wall,⁸ but in the report of some post-mortem examinations such adhesions were not found. Bouveret, in his recent monograph, holds that pulsation is met with whenever the resistance of the thoracic wall is greatly reduced, and Traube inclines to this belief. The indications for treatment seem to be, as in this case, complete evacuation and permanent drainage.

CASE 2.—W H P—, aged twenty six, clerk, who has been treated for pulmonary phthisis and whose family history is bad, sent an urgent message to me on May 18th, stating that "he had wrenched his inside" by assisting a dayman to "trestle a cask." He was in a prostrate condition when I arrived, vomiting and sweating profusely. Temperature 104.4°, pulse 130, thready. The pains in this instance were referred to the left side, which was fixed. A highly resonant note was obtainable over the front and side. Vocal resonance and vocal fremitus were absent. A sixth of a grain of morphia was given hypodermically and repeated in three hours, and the patient was enjoined to swallow a couple of teaspoonfuls of pale brandy in a little water. I resorted to fixation of the side by means of strapping, and this relieved the patient in no little degree—May 19th Patient expectorated some blood stained and mucoid sputum. Temperature 103°, pulse 130. Patient too ill and pain too great to localise the position of the heart—20th Signs of great intra thoracic pressure evident. Pulse very small, feeble, and rapid. Patient insists upon being allowed to stand or sit upright. Evening temperature 104°, pulse 140, left side distending, bell sounds well marked. The chest was punctured. A modification of Dieulafoy's aspirator was used, the contained air in the receiving bottle having been thoroughly exhausted, a quantity of gas was drawn off with about one ounce of fluid slightly streaked with blood. The heart moved to its original position—21st Patient improved, temperature 101°, pulse 120, respiration 28. Patient was not disturbed to examine the chest—22nd Expansion again evident, amphoric breathing with tinkling rales, and fluid has formed in the left pleura. Temperature 101°, pulse 120. There being no cyanosis or cardiac asthenia, tapping was deferred—23rd, 24th, 25th Symptoms and physical signs are the same as those of the 22nd—26th Symptoms became urgent and paracentesis was resorted to. A quantity of air came away and twelve ounces of fluid. From this date he improved, and in five weeks he was able to attend the surgery, when examination showed that the breath sounds, although weak, could be distinctly heard back and front. After this the patient went south and I saw no more of him.

Remarks—When a pneumothorax terminates in recovery the aperture in the lung must have healed and the gases been absorbed. As this takes place the pulmonary tissue is reinflated simultaneously, but recovery, at any rate partial, takes place most often in those cases which are circumscribed. The treatment of pneumothorax by aspiration is not advised by the leading authorities. Professor Gardner advocates puncture.⁹ Dr Clifford Beale thinks it is unadvisable to meddle with the chest unless the danger to life is immediate.¹⁰ Dr Douglas Powell advocates the introduction of the trocar when there are signs of pressure within the thorax,¹¹ but Dr Wilson Fox believes that it causes secondary effusion.¹² If the use of the trocar be accepted as the final treatment of the cardio asthenia of

ing a further collection of pus we explored again under chloroform and found pus at the bottom of the first sinus in a large cavity. A counter-opening was made in the back two full sizes and rubber drainage-tubes were passed from the front openings through it and the cavity was irrigated. The patient never really rallied and died on Nov. 9th, 1892.

The following is extracted from Dr. Munro's post mortem report. An abscess cavity extended from the anterior surface of the bladder which was covered with pus outside the peritoneum, along the iliac fossa and upwards to the under surface of the liver. The three openings made at different times all led into it. The second abscess cavity was between the obliquus internus and the transversalis muscles. No communication between the abscess sac and the peritoneum could be discovered, but from eight or ten ounces of pus were found in the pelvis and the intestines were glued together with purulent lymph. The cæcum and a portion of the ascending colon and ileum, with some surrounding tissue, were sent to me for dissection. The appendix vermiformis was glued to the posterior surface of the cæcum and the ascending colon. About half an inch from the cæcum it was perforated by a ragged ulcer. The perforation opened into the abscess cavity. The ulcer had nearly cut off the distal from the proximal end of the appendix. Both portions were perished. No concretion was found.

CASE 5.—A woman aged seventy was admitted to the Royal Infirmary, Newcastle-on-Tyne, on Aug. 20th, 1892, complaining of painful swelling in her bowels and weakness. Seven weeks before admission she first felt ill. She took to her bed five weeks ago. She then had some pain on the right side of the abdomen. Three weeks before admission a painful tender swelling was discovered by Mr. Martin of North Shields on the right side. Some diarrhoea was the only other symptom. She was a florid, emaciated, stout woman, looking extremely ill. Rapid feeble pulse, temperature 105° no appetite, dry tongue, considerable abdominal pain. Bronchial rales were detected on auscultation. The heart was hypertrophied. A systolic mitral murmur could be heard. The urine was normal in quantity and quality. The abdomen was distended and tender. On the right side there was a large, rounded tumour in the iliac fossa extending to the middle line below, to midway between the umbilicus and the anterior superior spine at the upper and inner border and above reaching to the lower costal margin. The patient was so ill and the abdomen so tender that no satisfactory examination was possible. From this time she improved, her temperature oscillating between 99 and 102°. The lung condition cleared up and she gained a little strength, though still very weak and ill. The mass on the right side softened and showed a tendency to point. No diagnosis could be made. On Sept. 1st, 1892, I opened the abdomen in the middle line, and introducing my hand found the bulk of the tumour to be a retro-peritoneal malignant mass surrounding and involving the cæcum. The pointing swelling was now punctured with a hypodermic needle in the right iliac fossa and pus was discovered. The median wound was closed and dressed and a drainage-tube left in a separate opening for the abscess cavity. The patient was returned to bed apparently no worse for the operation. The median wound healed in three weeks without any trouble. During September and the first half of October she improved in condition. Though profuse suppuration continued, and she was once out of bed. Then symptoms of increased cardiac failure showed themselves in breathlessness and oedema of the legs. On Oct. 23th, 1892, she complained of pain in the left leg which was noticed to be discoloured at its most dependent parts like post-mortem lividity. On the following day some of the reddened patches had turned black and there was no sensation in the foot and leg or pulsation in the arteries. On Nov. 2nd, in the evening she died somewhat suddenly. Before death total gangrene of the leg had occurred. Necropsy. There was contraction of the mitral orifice of a hypertrophied heart. No vegetations were detected on any of the valves. The left femoral artery was blocked for about six inches with an adherent blood-clot, white in the centre and red at the ends. There was a large malignant mass of glands behind the cæcum and surrounding it. The interior of the cæcum was extensively ulcerated, the ulcer having thick, hard walls. At the outer side and behind the cæcum and ascending colon a large abscess cavity extending from the pelvis to the under surface of the liver and diaphragm, was found. No secondary deposits were observed. Examined microscopically the growth proved to be a cylindroma.

St. Vincent's Newcastle-on-Tyne.

THREE CASES OF INTRA-OCULAR TUMOURS¹

By S. JOHNSON TAYLOR, M.B., C.M. EDIN. &c.

CASE 1.—A man aged sixty stated that, two months before consulting me, he had experienced a flickering in his left eye followed in three days by a loss of vision in the same organ, there was no pain or other disturbance. The sight of his right eye was fairly normal, whilst that of the left was less than counting fingers, the left pupil was a little larger than the right and only acted very slightly to light, the tension was normal or a full normal. The episcleral vessels in the middle line below were much enlarged and by focal light a dark brown mass far forwards was seen inferiorly and by careful focussing with the ophthalmoscope some small vessels could be seen on its surface, whilst to its nasal side the retina was clearly detached its vessels being seen with a convex lens of five dioptries. There was no evidence of any inflammatory mischief, nor did the mass move in any way with change of position, and I could clearly be accounted for only on one theory—viz., that of new growth, a gumma, a cyst, cercus, or a tubercular mass were all readily excluded. The great enlargement of the episcleral vessels over the site of the tumour was noteworthy. Such vascular dilatation is frequently found in growths on and near the ciliary region and is a very important sign, it occurred also in the next case. I urged the patient to allow his eye to be enucleated, but to that he would not consent. Some months afterwards I heard that the eye had been removed, but what valuable time was lost. No doubt secondary glaucoma, with intense pain, came on as the growth increased in size, and he submitted to the operation, the tumour was in all probability a melanotic sarcoma. Such a case is not uncommon. The next two cases are rare, one being exceptionally so.

CASE 2.—A woman aged sixty gave a history of increasing dimness of vision of the right eye since October 1890 and was first seen by myself in September 1891, when I found the vision 16 Jaeger with difficulty, the pupil, which acted to light was oval horizontally the iris tissue at its periphery above and below was gone and replaced by a patch of oar pigment, there were some large congested vessels on the sclerotic, one especially so below, the tension was normal. The pupil dilated badly with a mydriatic, the lens was so cataractous that only a dim view of the fundus could be obtained but looking very obliquely with the ophthalmoscope a murmur at the extreme periphery above and below the fairly regular rounded outline of a dark mass could be seen, though no vessels could be detected on it and rods all made out. Three days later I excised the eye, dividing the nerve far back, and up to the present—an interval of more than fifteen months—she has remained quite well. On opening the eye two separate growths in the ciliary region, one above, the other below were seen, each about the size of half a cherry stone. A full report by Mr. Collins of the microscopical examination will be found in the twelfth volume of the Transactions of the Ophthalmological Society.

CASE 3.—This case that of a woman aged fifty-two is also a very unusual one and I must confess I have never seen anything like it. There is no history of syphilis or tumours but she has had acute rheumatism three times, she has had eleven children, of whom nine are living. About ten years ago, after a fright, the sight of her right eye was noticed to be defective, almost as much so as it is at present. Of late she has had a feeling described as misery at the back of her head. I first examined her in November 1891, when the vision was only perception of light, with the pupil, anterior chamber and tension normal. Ophthalmoscopic examination revealed a rounded, well-defined, greyish white, solid looking mass occupying the centre of the fundus completely obscuring the optic disc and yellow spot and coming forward in front of the retina into the vitreous so that its most anterior part could be seen clearly with a convex lens of twelve dioptries. It could be isolated on all sides above below right and left, and the retinal vessels at several points could be seen emerging from beneath it, its surface in parts was supplied with a slate-grey pigment and at one or two points patches of nerviform vessels arranged in no definite way could be made

¹ Abstract of a paper read before the Norwich Medico-Chirurgical Society on Dec. 6th, 1892.

think I have proved my case as clearly as is possible in investigations of this kind. There are many difficulties to contend with in prosecuting these inquiries as the people in the neighbourhood of B— street &c. are easily led in conversation, and without considerable tact and discretion the information obtained is practically useless. The epidemic being small my difficulties were fewer and consequently the information is more trustworthy.

A bottle of the beer was purchased by me for bacteriological purposes, and I have endeavoured, without success up to the present, to cultivate colonies of the typhoid bacilli by inoculating agar and peptone with drops of the beer. I can hardly look upon want of success in this direction, however, as damaging my case, considering the present uncertain knowledge we possess of the typhoid bacillus.

FIVE CASES OF LAPAROTOMY PERFORMED ON PATIENTS OVER SEVENTY YEARS OLD

By J. RUTHERFORD MORISON, M.B. EDIN.,
F.R.C.S. ENG. & EDIN.,

SENIOR ASSISTANT SURGEON, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

LONG lists of successful ovariectomies can no longer serve any good purpose, for it has been proved that the mortality of ovariectomy should not exceed 5 per cent. My excuse for publishing the following cases is the advanced age of the patients. Sir G. M. Humphry long since pointed out that in old people repair and recovery are likely enough to follow major operations. This is true of abdominal section,—a fact not sufficiently recognised. My list includes all the patients over seventy on whom I have performed abdominal section, five in number. Four of them had ovariectomy successfully performed. Three of these are well and active at the present time. One died nearly two months after operation from the results of appendicitis. The fifth recovered from an exploratory abdominal section made to ascertain the nature of, and to treat if possible, an abdominal tumour of doubtful character and origin.

CASE 1.—A widowed seventy was sent to me in December, 1890, by Dr. McBean, with a cystic tumour in the abdomen. For several months she had noticed a growing swelling, had lost flesh and strength, and had been troubled with a hæmorrhagic vaginal discharge. The patient was a thin, wiry looking old lady, very nervous but cheerful. Nothing was found wrong except in the abdomen which was distended to about the size of a six months pregnancy. The distension was due to a fluctuating tumour fixed below in the pelvis. The left fornix was bulged by an elastic fixed tumour pushing the uterus over to the right. On Dec. 22nd, 1890, I performed the following operation. A broad ligament cyst was exposed, tapped, and enucleated after dividing the peritoneum covering it. The hæmorrhage was arrested by tying each bleeding point as exposed. A large raw surface was left, over which the stripped peritoneum was laid. The operation occupied one hour. Drainage was employed for three days. The patient recovered so rapidly that she was allowed to get up on the tenth day, and went home well in a fortnight.

CASE 2.—A widow aged seventy four came to me in August, 1892. The patient discovered an abdominal swelling herself ten years ago and consulted a medical man, who said it contained fluid. The swelling had steadily increased in size, but except by its weight had caused no discomfort. She had had no teeth since she was thirty years of age, and was never robust. All her family were short-lived. The patient was a thin, anxious looking woman with wrinkled skin and brown hair turning grey. Nothing was discovered abnormal except in the abdomen, which was rounded, prominent and larger than a full time pregnancy. A large, well defined cystic tumour was the cause of the swelling. It filled the abdomen so completely as to appear immovable, but friction could be felt over it on pushing it from side to side and during forced respiration. The tumour could be felt in front of and distinct from the uterus. On Aug. 6th, 1892, I removed a large cystic ovarian tumour free from adhesions. The after progress was uneventful. On the ninth day the dressings were taken off for the first time and the sutures taken out. The wound had entirely healed by first intention. On the fifteenth day the patient went home well.

CASE 3.—A widow aged seventy two, under the care of

Dr. Oliver, seventeen months ago noticed a "lump" in the lower part of the bowels. There was no pain, but "the womb came down." Four months ago the tumour began to increase in size and rapidly became larger. The uterus now troubled her and she noticed a coloured vaginal discharge which had increased during the last four or five weeks. The weakness produced by this was her chief complaint. Her health since she attained the age of forty five years had been fair. Up to that time she suffered from bilious attacks. She was a trim, bright-complexioned old lady with iron grey hair and a senile cataract in her right eye. Her heart was hypertrophied, as was shown by a diffused and heaving apex beat. The arteries were rigid and tortuous, the lungs were healthy. The urine was normal in quantity, sp. gr. 1005, a trace of albumen was present. The skin of the abdomen was much pigmented, especially over the upper part, and the superficial veins were dilated. The abdomen was made prominent by a rounded cystic thin walled tumour, flaccid and apparently unilocular, about the size of a large football. It was freely movable from side to side, but not from below upwards. The anterior wall of the vagina was prolapsed and the anterior cul de sac filled by a rounded elastic tumour. The left fornix was bulged out by the swelling. On the right side a hard nodular swelling was connected with the tumour. The uterus lay behind and was free from the tumour. On Sept. 8th, 1892, I performed the following operation. A flaccid cyst of the right ovary containing about one gallon of very thick glairy fluid was removed. The left ovary, with a hard tumour about the size of a walnut growing from it, was also taken away and the abdominal wound entirely closed. Subsequent progress was most satisfactory. The dressing was changed for the first time on the tenth day after the operation, when the stitches were taken out. The wound healed by first intention except at one place about half an inch long, where the skin had become inverted and granulations were visible. This healed a few days afterwards. On the tenth day the patient left her bed, and on the fifteenth she went home.

CASE 4.—A widow aged seventy seven, a patient of Dr. Munro of Burnard Castle. For years her abdomen had been large. She was suddenly seized with pain in the right iliac fossa, vomiting and shivering. The pain soon afterwards extended to the right leg, preventing her from straightening it. The bowels had been confined and she had been feverish and sweating at nights during the whole illness. The day previous to my visit Dr. Munro and Dr. Drummond found, by means of a hypodermic syringe, fetid pus in the right iliac fossa. Thirty three or thirty four years ago she had a dangerous illness—"inflammation of the bowels"—on the right side. She had never been robust but usually healthy. The patient was a thin, dark woman, who looked ill, with high temperature, tender swollen abdomen and oedematous legs, the right leg was more swollen than the left. An operation was performed on Sept. 20th, 1892. On opening the abdomen in the right iliac semilunar an ovarian tumour the size of a football was exposed and removed. No pus was found in it and there was nothing about it to account for the patient's serious condition. The cæcum, which Drs. Munro and Drummond had suspected to be the cause of the mischief, was now examined. It was adherent to the parietes and a fluid collection could be felt behind and to its outer side extending back to the loin. A second incision above the centre of the crest of the ilium allowed the escape of fully six ounces of fetid pus. The anterior or ovariectomy wound was sutured and the lateral wound drained with a glass tube, each wound being separately attended to and dressed. The ovariectomy wound never gave any trouble and quickly healed. Until Oct. 8th the after progress was most satisfactory, the general condition improved with return of appetite, sleep and freedom from pain. On this date the glass tube could not be replaced by the nurse, Dr. Munro or myself and for the first time since the operation her evening temperature was over 100°—Oct. 9th. No discharge from sinus, evening temperature 103°—12th. A gush of pus from sinus with lowered temperature.—Recurrences of a similar sort took place till Oct. 20th, when a fresh tender lump was noticed.—25th. Under chloroform I freely opened an abscess which extended from the iliac crest to the costal margin. The cavity appeared to be between the muscular margin of the abdominal wall and contained about four ounces of pus. Improvement followed and the patient was able to be out of bed. Soon, however, she relapsed, with some evening rise of temperature.—Nov. 5th. Dr. Munro suspect

ing a further collection of pus we explored again under chloroform and found pus at the bottom of the first sinus in large cavity. A counter-opening was made in the back, two all sized india-rubber drainage-tubes were passed from the front openings through it and the cavity was irrigated. The patient never really rallied and died on Nov. 9th, 1892.

The following is extracted from Dr. Munro's post mortem report. An abscess cavity extended from the anterior surface of the bladder, which was covered with pus, outside the peritoneum, along the iliac fossa and upwards, to the under surface of the liver. The three openings made at different times all led into it. The second abscess cavity was between the obliquus internus and the transversalis muscles. No communication between the abscess sac and the peritoneum could be discovered, but from eight to ten ounces of pus were found in the pelvis and the intestines were glued together with purulent lymph. The cæcum and a portion of the ascending colon and ileum with some surrounding tissue, were sent to me for dissection. The appendix vermiformis was glued to the posterior surface of the cæcum and the ascending colon. About half an inch from the cæcum it was perforated by a ragged ulcer. The perforation opened into the abscess cavity. The ulcer had nearly cut off the distal from the proximal end of the appendix. Both portions were pervious. No concretions were found.

CASE 5.—A woman aged seventy was admitted to the Royal Infirmary, Newcastle on Tyne, on Aug. 20th, 1892, complaining of painful swelling in her bowels and weakness. Seven weeks before admission she first felt ill, she took to her bed five weeks ago, she then had some pain on the right side of the abdomen. Three weeks before admission a painful tender swelling was discovered by Mr. Martin of North Shields on the right side. Some diarrhoea was the only other symptom. She was a florid, cyanosed, stout woman, looking extremely ill. Rapid feeble pulse, temperature 106°, no appetite, dry tongue, considerable abdominal pain. Bronchial rales were detected on auscultation. The heart was hypertrophied. A systolic mitral murmur could be heard. The urine was normal in quantity and quality. The abdomen was distended and tender. On the right side there was a large, rounded tumour in the iliac fossa extending to the middle line below, to midway between the umbilicus and the anterior superior spine at the upper and inner border and above reaching to the lower costal margin. The patient was so ill and the abdomen so tender that no satisfactory examination was possible. From this time she improved, her temperature oscillating between 98° and 102°. The lung condition cleared up and she gained a little strength, though still very weak and ill. The mass on the right side softened and showed a tendency to point. No diagnosis could be made. On Sept. 1st, 1892, I opened the abdomen in the middle line, and introducing my hand found the bulk of the tumour to be a retro peritoneal malignant mass surrounding and involving the cæcum. The pointing swelling was now punctured with a hypodermic needle in the right iliac fossa and pus was discovered. The median wound was closed and dressed and a drainage-tube left in a separate opening for the abscess cavity. The patient was returned to bed apparently no worse for the operation. The median wound healed in three weeks without any trouble. During September and the first half of October she improved in condition, though profuse suppuration continued, and she was once out of bed. Then symptoms of increased cardiac failure showed themselves in breathlessness and oedema of the legs. On Oct. 30th, 1892, she complained of pain in the left leg which was noticed to be discoloured at its most dependent parts like post-mortem lividity. On the following day some of these reddened patches had turned black and there was no sensation in the foot and leg or pulsation in the arteries. On Nov. 2nd, in the evening, she died somewhat suddenly. Before death total gangrene of the leg had occurred. Necropsy. There was contraction of the mitral orifice of a hypertrophied heart. No vegetations were detected on any of the valves. The left femoral artery was blocked for about six inches with an adherent blood clot, white in the centre and red at the ends. There was a large malignant mass of glands behind the cæcum and surrounding it. The interior of the cæcum was extensively ulcerated, the ulcer having thick, hard walls. At the outer side and behind the cæcum and ascending colon a large abscess cavity, extending from the pelvis to the under surface of the liver and diaphragm was found. No secondary deposits were observed. Examined microscopically the growth proved to be a cylindroma.

THREE CASES OF INTRA-OCULAR TUMOURS¹

By S. JOHNSON TAYLOR, M.B., C.M. EDIN. &c.

CASE 1.—A man aged sixty stated that, two months before consulting me, he had experienced a flickering in his left eye, followed in three days by a loss of vision in the same organ, there was no pain or other disturbance. The sight of his right eye was fairly normal, whilst that of the left was less than counting fingers, the left pupil was a little larger than the right and only acted very slightly to light, the tension was normal or a full normal. The episcleral vessels in the middle line below were much enlarged and by focal light a dark brown mass far forwards was seen inferiorly, and by careful focussing with the ophthalmoscope some small vessels could be seen on its surface, whilst on its nasal side the retina was clearly detached its vessels being seen with a convex lens of five dioptries. There was no evidence of any inflammatory mischief nor did the mass move in any way with change of position, and it could clearly be accounted for only on one theory—viz., that of new growth, a gumma, a cysticercus, or a tubercular mass were all readily excluded. The great enlargement of the episcleral vessels over the site of the tumour was noteworthy. Such vascular dilatation is frequently found in growths of and near the ciliary region and is a very important sign, it occurred also in the next case. I urged the patient to allow his eye to be enucleated, but to that he would not consent. Some months afterwards I heard that the eye had been removed, but what valuable time was lost. No doubt secondary glaucoma, with intense pain, came on as the growth increased in size, and he submitted to the operation, the tumour was in all probability a melanotic sarcoma. Such a case is not uncommon. The next two cases are rare, one being exceptionally so.

CASE 2.—A woman aged sixty gave a history of increasing dimness of vision of the right eye since October 1890 and was first seen by myself in September, 1891, when I found the vision 16 Jaeger with difficulty, the pupil, which acted to light, was oval horizontally, the iris tissue at its periphery above and below was gone and replaced by a patch of dark pigment, there were some large congested vessels on the sclerotic, one especially so below, the tension was normal. The pupil dilated badly with a mydriatic, the lens was so cataractous that only a dim view of the fundus could be obtained, but looking very obliquely with the ophthalmoscopic mirror at the extreme periphery above and below the fairly regular, rounded outline of a dark mass could be seen, though no vessels could be detected on it and no details made out. Three days later I excised the eye, dividing the nerve far back, and up to the present—an interval of more than fifteen months—she has remained quite well. On opening the eye two separate growths in the ciliary region, one above, the other below, were seen, each about the size of half a cherry stone. A full report by Mr. Collins of the microscopical examination will be found in the twelfth volume of the Transactions of the Ophthalmological Society.

CASE 3.—This case, that of a woman aged fifty two is also a very unusual one, and I must confess I have never seen anything like it. There is no history of syphilis or tumours but she has had acute rheumatism three times, she has had eleven children, of whom nine are living. About ten years ago, after a fright the sight of her right eye was noticed to be defective almost as much so as it is at present, of late she has had a feeling described as "misery" at the back of her head. I first examined her in November 1891 when the vision was only perception of light, with the pupil, anterior chamber and tension normal. Ophthalmoscopic examination revealed a rounded, well defined, greyish white solid looking mass occupying the centre of the fundus, completely obscuring the optic disc and yellow spot and coming forward in front of the retina into the vitreous, so that its most anterior part could be seen clearly with a convex lens of twelve dioptries. It could be isolated on all sides above, below right and left, and the retinal vessels at several points could be seen emerging from beneath it, its surface in parts was stippled with a slate grey pigment and at one or two points patches of newly formed vessels, arranged in no definite way, could be made

¹ Abstract of a paper read before the Norwich Medical Surgical Society on Dec. 6th, 1892.

out. It was clearly growing in front of the retina and choroid, and my own idea was that it was growing from the face of the optic disc, possibly from the remains of a foetal structure such as the hyaloid artery, and that it was of myxomatous or more fibrous connective tissue type and of comparatively innocent nature.

It was suggested at one of the meetings of the Ophthalmological Society at which I brought forward the patient that the growth might be of a colloid nature. I have urged enucleation as the eye is useless and a possible source of danger to life, but up to the present she has not consented to have it removed. I venture to say that the last two cases are amongst the rarest to be met with anywhere.

Prince of Wales road, Norwich.

TREATMENT OF A CASE OF PYÆMIA RESULTING FROM DISEASE OF THE MIDDLE EAR

By BERNARD SCOTT, M.R.C.S., L.S.A.,

AND

W. ARBUTHNOT LANE, M.S., F.R.C.S.

Mrs. S—, aged forty, had been troubled for more than four years by an offensive purulent discharge from the left ear, for which she had been treated without deriving much benefit from the treatment. At intervals she suffered from attacks of pain in the ear and in the mastoid process and its vicinity, together with headache on the left side of the head. About the middle of April, 1892, the patient had one of these attacks which was more severe in its character than those preceding it, the headache accompanying the local pain being very great. This continued with increasing tenderness over the mastoid process. On May 29th she suddenly became much worse and had a rigor. Mr. Bernard Scott of Bournemouth was then called in to see her and at once suggested operative interference, as he believed she had a subdural abscess in the posterior fossa. On the 30th she was much better, but could not bear any light. This rendered any examination of the fundus of the eye impossible. On the 31st the patient had another rigor, the temperature rising to 104.5°. Mr. Scott now came to the conclusion that the sinus had become involved by a septic thrombosis and again urged the advisability of surgical interference without delay. This the friends opposed as the patient rapidly improved. On the following day the temperature was normal and the headache was much less. On June 2nd she had another rigor, when Mr. Scott asked Mr. Arbuthnot Lane to see the patient with him, which he did in the evening. Mr. Lane quite agreed with Mr. Scott as to the presence of a subdural abscess of some size with septic thrombosis of the lateral sinus and it was decided to operate at once. Some small cancellated spaces filled with pus were found in the mastoid process, which accounted for the local pain and great tenderness which existed, neither of which symptoms are of necessity present in subdural abscess with or without a septic thrombosis of the lateral sinus. The antrum was found to be much enlarged and to be filled with foul smelling pus. On freely exposing the dura mater of the posterior fossa a large subdural abscess was opened. This abscess extended over the lateral sinus for about an inch and a half, the wall of the sinus was, like that of the adjacent dura mater, much inflamed. Bone was freely removed with the gouge till the sinus was fully exposed for more than two inches, healthy dura mater and sinus being bared for some distance beyond the limit of the subdural abscess. On introducing a needle into the sinus, blood flowed freely. The internal jugular vein was then tied in the neck and the wound closed accurately with a continuous suture. On again pricking the sinus, blood did not flow, showing that the sinus was blocked at the torcular limit of the subdural abscess. The inflamed wall of the lateral sinus up to the torcular margin was cut away with scissors, when a large conical shaped clot about an inch and three quarters in length was pulled out of the sinus and internal jugular vein into which it extended. Having prepared a large plug formed of iodoform and gauze the sharp spoon was quickly introduced into the sinus and the small thrombus which closed it was removed. Very pro-

fuse hæmorrhage followed this step of the operation, but it was readily controlled by the plug of gauze. Owing to the very free hæmorrhage it would have been impossible to introduce any plug into the sinus had it seemed advisable to do so, but this was quite unnecessary, as the mass of gauze and iodoform which pressed on the open aperture of the sinus prevented further hæmorrhage. The skin flaps were then sewn down over the iodoform and gauze, so as to retain it in firm apposition. Previously to this the contents of the middle ear had been removed. The relief afforded by the operation was most marked, the patient sleeping without any sedative, the headache and local pain also disappearing. The iodoform plug was removed seventy two hours after the operation and all the skin incisions were healed by first intention. The temperature never rose above 99° after the operation and in a fortnight the patient was sitting up and enjoying her meals.

This case, like hundreds of others, but too clearly proves the folly of delay in performing antrectomy when a patient with chronic middle-ear disease begins to be affected by pain in and about the mastoid process and by headache limited more or less completely to one side of the head. In such a case no other surgical treatment is so effectual, for the operation, though unaccompanied by risk in its performance, frees the patient from immediate pain and discomfort as well as from all subsequent risk, and at the same time restores to the patient more or less perfect hearing capacity.

The only point in the treatment of this case which is possibly novel was the complete removal of that portion of the thrombus which blocked the lateral sinus at the torcular limit of the subdural abscess. The readiness with which the very free flow of blood which then followed was permanently controlled by the pressure of the gauze plug was remarkable. At the same time it was obvious that if the whole lumen of the sinus had not been more or less completely thrombosed at one point, and that distally, great difficulty would have been experienced in opening up the sinus sufficiently freely to allow of the complete removal of a partial thrombus in the face of the very free hæmorrhage which would have resulted from an incision into the sinus. Though many methods of treatment have proved successful in these cases of thrombosis of the lateral sinus accompanied by rigors, and later by secondary abscesses &c., yet it would appear that the method here adopted of removing every portion of the thrombus is, if possible, the most scientific and perfect, and Mr. Lane followed it with equally satisfactory results soon after in another case.

That such a complete removal is by no means necessary for recovery is shown by the different means which were adopted in the three following cases operated on by Mr. Lane. Case 1. Internal jugular vein ligatured, lateral sinus opened and cleared of proximal portion of clot, distal portion of clot being left because very close to torcular, recovery. Case 2. Internal jugular vein tied, surface of sinus cleared of pus but not opened, recovery. Case 3. Subdural abscess, rigors, partial thrombosis, abscess cleared out, recovery.

Out of six cases of pyæmia due to middle-ear disease on which Mr. Lane had operated he had lost only one, and death arose in that case from an extension of the septic process along the petrosal to the cavernous sinuses. Mr. Horsley, in a paper¹ published in the Clinical Society's Transactions, 1886, threw out a suggestion that in cases of septic thrombosis of the lateral sinus the internal jugular vein should be tied, but he did not propose to interfere with the thrombus itself. It was in consequence of this suggestion that Mr. Lane performed his first operation, though in this case, besides ligaturing the internal jugular vein, he removed thoroughly almost the entire thrombus. To trust to ligature of the internal jugular vein alone would be inadvisable, as the thrombus may readily creep along the petrosal and lateral sinuses, and it is well to remove it in its entirety. This applies with increased weight to cases of septic thrombosis arising in other portions of the body and is well illustrated by a case² which was recently published in THE LANCET by Mr. Lane.

Mr. Rushton Parker, in a most interesting account of his case,³ speaks of probing the sinus upwards and blood escaping freely. One does not gather, however, from his

scription that he did this with the view of removing every portion of clot, though in all probability that as the motive that guided him in doing so. Unfortunately too often septic thrombosis of the lateral sinus and the usually necessary antecedent condition (subdural effusion) escape notice till too late, because the surgeon expects to find tenderness or swelling of the mastoid process, and on percussing over that bone, tenderness or swelling along the course of the internal jugular vein &c., none of which are necessarily symptoms of these conditions. The reason of this has been pointed out fully in an abstract of medical lectures on inflammation of the middle ear and its implications which was published in THE LANCET of Sept 26th, 1891.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL

THREE CASES OF FRIEDRICH'S DISEASE

By E. H. BROCK, M.D., B.S. LOND.

Family history—The father of Cases 1 and 2 is alive and healthy, he had one sister who died in middle life and who is said to have been affected similarly to the cases here described. Their mother is alive and healthy and has had fifteen children, of whom eight died in infancy, of the other seven, four were boys and three were girls. Of the three girls, one died aged thirty one affected similarly to the cases here described, the second is married and has four children, three boys and one girl, the eldest boy, aged fifteen, being affected (Case 3), and the third is married and has five children, all healthy. Of the four boys, one is married and has nine children, five boys and four girls—of these, one of the girls, aged sixteen, has very marked lateral curvature and suffers from asthma. The second (Case 1) is married and has four children, three boys and one girl—one of the boys, aged ten, is said to have had health, he has attacks of weakness of the arms and legs, especially the latter, during which he is unable to get about or to dress himself the attacks passing off in the course of a day, after which he seems all right. Physical examination of this patient does not reveal anything significant of disease, his knee jerks, muscular development, sensation, gait, eyes &c. all appearing normal. The third is single and healthy, and the fourth, who is married (Case 2), has no family.

Case 1—S. S.—aged forty. Has been married sixteen years, and was formerly a stonemason. Complained mainly of inability to walk. He was quite healthy till eighteen years of age, when having been working as a stonemason for four years it was noticed that his right shoulder was "growing out." He sought advice and after getting worse for a time it became stationary. About four years later he gave up his work as a stonemason, partly from the fact that he used frequently to strike his hand with the mallet. A few months later he came to London and obtained a situation as foreman in a brick field. Whilst thus engaged he began to notice some difficulty in walking in the dark, he seemed to "go all over the place." The difficulty was especially marked in ascending or descending steps the latter being worse. About this time he had occasional violent headache. He married, and about two years after coming to London he returned to the country and tried to work in a stone quarry. He very soon, however, had to use a stick in walking and said his legs used to "catch," and he could not understand how it was he always seemed to lift his feet too high. The difficulty in walking had gradually increased and for the last three years he had been quite incapacitated. His wife thought his speech had gradually become less distinct and this was especially remarked by his friends who saw him at infrequent intervals. At times he had difficulty in holding his urine, but did not wet the bed. The patient was very well nourished, he was easily excited to laughter, the speech was thick and indistinct sometimes being quite unintelligible, the nodding movements of the head were very marked,

especially when the patient was first spoken to. There was very slight slow nystagmus sometimes observable when he looked to the extreme right or left, the pupils and optic discs were normal. He suffered from slight weakness of the legs and the hands. There was very marked incoördination of the arms as when directed to touch the end of his nose or pick up a pin. The knee jerks were absent, the plantar reflex was present, cremasteric and abdominal reflexes were not obtained, there was no loss of common sensation. He could just stand with assistance and an attempt to walk was markedly ataxic, the knees being over extended. He had no lightning or girdle pains and there was no rigidity of the legs or arms. The patient had marked lateral curvature of the spine to the right in the upper dorsal region, to the left below.

Case 2—C. S.—aged twenty seven, married. This patient said that he had always had more or less difficulty in walking in the dark and in going up and down stairs. This difficulty had become greater during the last twelve years. He was well nourished, his speech was slow, drawing and indistinct, the nodding movements of the head were present, there was slight slow nystagmus on looking to the extreme right or left, the pupils and optic discs were normal, knee-jerks were present, there was no rigidity of the legs, no ankle clonus, no alteration in common sensation, the walk was markedly ataxic, there was also incoördination of the hands and arms.

Case 3—F. B.—aged fifteen, schoolboy, nephew of the preceding. He said that there was nothing the matter with him. His walk, however, was slightly ataxic, the feet being kept well apart, and he had considerable difficulty in turning round quickly, he also swayed considerably and almost fell when walking or standing with the eyes shut, the pupils and optic discs were normal, the speech was natural, though rather slow, there were no nodding movements of the head, knee-jerks were absent, there was no impairment of sensation and no rigidity, he had incoördination of his hands and arms, as in touching his nose or picking up a pin, and said that when trying to play football he almost always missed the ball.

Bridge-terrace, Maldstone

ON MIGRAINE

By LEONARD G. GUTHRIE, M.B. & B.Ch. OXON,
M.R.C.P. LOND. &c.,

PHYSICIAN TO THE REGENT'S-PARK HOSPITAL FOR PARALYSIS ASSISTANT
PHYSICIAN TO THE NORTH WEST LONDON HOSPITAL AND
PADDINGTON-GREEN CHILDREN'S HOSPITAL.

DR. WALLACE's graphic account of his sufferings from migraine and of their cure by simple means, published in the last issue of THE LANCET, recalls a similar episode in the "Mémoires de Marmontel" (born 1723, died 1799). Marmontel writes—"Although my health as a rule was perfectly good, I was subject to headaches of a very peculiar kind. The disease is called 'clavus,' its locality just beneath the eyebrow. It is the throbbing of an artery whose every pulsation pierces like a knife thrust to one's soul. The pain is inexpressible, yet, excruciatingly intense as it is, it affects one spot only.

For seven years this illness came upon me at least once a year and lasted twelve to fifteen days, not continuously, but in fits as happens in fevers, and each day at almost precisely the same time. Each fit lasted about six hours, announcing itself by a feeling of tension about the veins and neighbouring fibres, and by not more hurried but stronger throbbings of the artery where the pain was situated."

—Medical men had striven in vain to cure him. Bark, bleeding, fumigation, sternutories and musk made him worse. Even the Queen's own doctor "Malouin" ("a fairly clever man, but more Purgon than Purgon himself") failed to relieve him by injections of "infusions de vulnéraire." At last one day during the height of an attack "Genson," the Dauphin's farmer and celebrated veterinary surgeon, happened to call. "He saw the inflamed state of my right eye and all the fibres of my temple and eyelid quivering and palpitating and asked the cause of my illness. I told him what I knew about it, and after a few details as to my constitution, mode of living and usual state of health he said 'Is it possible you have been allowed to suffer so long from an illness which might so easily have been cured? When your ink is too thick and will not flow, what do you do?' 'Put water to it.' 'Well, put water

to your lymph, it will then flow and no longer congest the pituitary membrane which at present obstructs the artery, whose pulsations rub upon the neighbouring nerve and cause you such great pain. You have in the bone there a small cavity called the 'frontal sinus' lined by membrane which is now thickened and congested. What we have to do is to get it clear. Be careful at dinner to day. Take no stewed meats or neat wines, coffee or liqueurs, and instead of supper to night drink as much fresh clear water as your stomach can bear without fatigue. To-morrow morning drink water in the same way. Keep to this diet for a few days, and I predict that to-morrow the attack will be slight, the day after to-morrow scarcely perceptible, and on the following day there will be no attack at all."

The prediction was verified, and as to prevention the learned veterinarian warned him that for some years thickened lymph would tend to accumulate in the weakened mucous membrane of the frontal sinus. If he would observe the premonitory symptoms (tension of veins and fibres of the temple and eyebrow) and then drink water and resume the diet, he would both relieve the pain and in time would prevent recurrence of the disease. "His rules were strictly observed, and I obtained to the full the result he had promised me."

Genson's pathology is crude, but his treatment is similar in method and success to Dr Wallace's own. Indeed, one may question whether Dr Wallace's relief was due to "salvolatile, soda, ginger, peppermint and chloroform" or to the two or three tumblers of cold water in which they were taken, combined with restricted diet. Some agree that the success which attends drinking Spa waters probably depends less on their nastiness than on the quantities in which they are drunk, together with the hygienic régime enjoined. Yet our patients will not usually drink water unless we make it nasty for them, and had Genson been a physician Marmontel would probably have rejected his advice with scorn. Both Dr Wallace and Marmontel speak of that form of migraine which is due to imperfect elimination of waste products, and which is cured by the homely expedient of "flushing the drains." Migraine may sometimes be a pure neurosis or "nerve storm," but in most cases the wind is raised by the stomach and digestive organs generally. Yet there are many other causes of migraine. Errors of refraction are well known to produce it, especially in childhood. This was my own case in early youth. Again, various local conditions of the nasal passages and sinuses, such as catarrh, inflammation, necrosis, polypi, or foreign bodies, may give rise to the complaint. Foreign bodies may be living. Scoutetten¹ speaks of a Metz farmer who for a year had suffered from the most terrible of headaches, in which the temporal arteries pulsed violently, the eyes and nostrils ran and the least noise or light could not be borne. He became delirious during the paroxysms, which occurred five or six times a day and as often at night. At last his sufferings were relieved by the expulsion through the nose of living "scelopendra electrica" two inches and a quarter in length. Again, as Dr Lauder Brunton has ably shown ("Disorders of Digestion"), many headaches are due to dental caries. A girl aged thirteen has been under my care for eighteen months. For a year previously she had suffered from the interesting combination of symptoms—weekly migraine, monthly epilepsy and more or less constant tetany² of both hands and feet. Her digestion was bad, her front teeth were decayed and she had also punctate cataract, to which I at first attributed the symptoms. However, on getting the teeth stopped and giving instructions as to diet and exercise (which were carried out with Spartan like rigour), she had only one more fit within a month and has had none since. The tetany and headaches gradually disappeared and for many months she has appeared in perfect health. Avoidance of a particular cause will sometimes prevent migraine. To this day I dare not walk between thin hedges or vertical close set palings through which a bright sunlight flickers, for if I do giddiness, hemianopsia and violent headache invariably occur. Neither can I use a catalogue in a picture gallery, except for pictures on the line. The frequent and sudden alterations of accommodation entailed speedily produce typical migraine, which, however, I escape if I am without a catalogue. Hence in all cases of migraine it is needful to follow Marmontel Genson's example and inquire into the "habits, constitution and general health" of the patient before prescribing a universal cure-all.

Upper George-street, W

THE POSOLOGY OF THE PHARMACOPEIA

By R. J. BLACKHAM, L.R.C.P., L.R.C.S. EDIN &c.,
SURGEON TO THE TON AND BULLFA COLLIERIES.

THE doses of the Pharmacopœia have often been questioned, but I think the most glaring error in the book is the dose of the official substitute of chlorodyne—the tinctura chloroformi et morphine. The maximum dose of this remedy is given as ten minims, but I have never obtained any substantial benefit from less than twenty or thirty minims. I may quote the following case in illustration both of this fact and of the somewhat erroneous statement of the text-books that opium is very badly borne by children.

A few days ago I was called to see M. L., aged six years, who was suffering from the following symptoms. She had been vomiting for some hours, and was obstinately constipated, the temperature was 102°, pulse 130, the abdomen was hard and board like but very slightly tender, and she lay supine with the legs drawn up, complaining of intense pain referred to the umbilical region. I ordered turpentine stupes and administered two minims of the tincture of opium, with four of the tincture of henbane every hour, but without substantial benefit. As the turpentine rapidly affected the delicate skin of the child I was obliged on the third day to substitute linseed meal poultices. These, while very warm, eased the pain temporarily. On the morning of the fourth day I found the child had stood the opium remarkably well, the pupils remaining fairly large, and the patient by no means drowsy. She only slept for periods of not more than half an hour, and invariably woke in great agony. I determined to try the Galenical chlorodyne on the evening of the fifth day, commencing with five minims every hour while in pain. It acted like a charm, soothing the little patient immediately. I combined it with two-minim doses of the tincture of belladonna and gave the mixture freely. On the ninth day, after consuming almost five drachms of the tincture of chloroform and morphine without fifty six hours, the child was quite free from pain, its temperature was normal and its appetite and spirits good. She has now quite recovered. I should mention that I administered a teaspoonful of malted rice on the third fifth and eighth days and supported the child solely on milk and beef tea, giving iced imperial drink to allay the thirst, which was very considerable. I consider the case instructive as it teaches us something of the therapeutics of a valuable compound and militates strongly against the official posology and the generally taught opinion that opium and its compounds are invariably badly borne by young children.

Ton Pentre, Rhondda Valley, S. Wales

DIABETES FOLLOWING INFLUENZA, RECOVERY

By G. H. HETHERINGTON, M.R.C.S., L.R.C.P. LOND.,
AND
HERBERT H. BROWN, M.D., B.S. LOND., F.R.C.S. ENG.

CASES of complete recovery from acute diabetes mellitus occurring in a young subject are of sufficient rarity to be worthy of record. The following case resembles very closely one which was recorded in THE LANCET (April 2nd, 1892, in which, as in this case, diabetes supervent upon an attack of influenza.

On March 10th, 1892, a boy fifteen years of age came to consult us with the following history. He had been quite well until a month previously, when he was attacked by influenza. Three weeks ago he began to suffer from thirst. This steadily increased and was a very distressing symptom when he sought advice. His urine began to increase in amount *pari passu* with the thirst, and he had to get eight or nine times in the night to pass urine. The total amount for the twenty-four hours would appear during the last few days to have been from twelve to fifteen pints. He had rapidly lost flesh and strength. There was no history of diabetes in the family. His father, mother five brothers and two sisters are alive and well. The lad was thin and nervous and rather tall for his age, face slightly flushed, aspect suggestive of diabetes, tongue red, clean, and smooth, and pale, of typical diabetic appearance, loaded with sugar, sp. g. 1040. An absolutely strict diabetic diet was ordered, and

urbo-hydrates so far as possible being excluded. Under this regimen the patient improved at once. The next day the urine was gone, and only sixty ounces of urine were passed, *s. p. gr.* 1035. After one week the daily excretion was about sixty-five ounces of *s. p. gr.* 1030 still containing sugar, though in greatly diminished amount. He was then given half a grain of codeia three times daily immediately after meals. Two days later, nine days from the commencement of treatment, the sugar entirely disappeared. Since that date (March 19th) the urine has remained absolutely free from sugar, and the patient has completely regained health and strength. The codeia was first reduced on May 7th to one grain and on the 21st to half a grain daily. In the first week of June the diet was gradually relaxed, until by the end of that month the patient returned to his ordinary food and the codeia was left off altogether.

A very similar case to the above was reported in THE LANCET of April 2nd, 1892, by Mr. Hoysted. Acute diabetes came on a week after influenza and disappeared entirely upon treatment by dieting and codeia. As regards the pathology little can be said. When first seen the case appeared to be one which might terminate fatally in a comparatively short time, and if untreated probably would have done so. The attack followed very closely upon influenza, and, taking the other case into consideration, it is impossible to resist the inference that it was a sequela of it. It is possible that several such cases may have occurred during the recent epidemics. On the other hand, influenza occurring in a diabetic patient does not necessarily aggravate the disease. In one case of severe diabetes, at a time in which by careful dieting and treatment by codeia the urine was kept free from sugar it remained so during an attack of influenza and for several weeks afterwards, although during the febrile period a milk diet was principally used. It is probable that diabetes following influenza, though very acute in its onset and doubtless if untreated rapidly tending to a fatal termination, yet differs from the ordinary form in its special amenability to treatment.

Ipwich.

AN UNCOMMON CAUSE OF DEAFNESS

By C. F. WILLIAMSON, M.R.C.S., L.R.C.P. LOND. &c.

I THINK the following case of deafness is of sufficient interest to be published in THE LANCET on account of its rarity.

Recently I was asked to see a boy aged six years who was suffering from neuralgia, otorrhoea and deafness. On examination there were a slight discharge, not offensive, issuing from the external meatus total deafness and a dark object filling up the passage. No history could be extracted of anything having been introduced into the ear. All attempts at a second examination were repulsed and as I was some distance from my house I desisted intending to give an anæsthetic the following day. Next morning on examination, I found a foreign body presenting at the meatus, which was easily removed by a bent probe, and proved to be a blowfly complete except for its wings. When the mother of the child saw the fly she said that eighteen months previously she attended a sale, taking her son with her. While there he caught a fly by its wings and kept constantly holding it up to his ear to hear it buzz. After a short time the wings became detached and the fly crawled into his ear. All that night the boy cried with earache, but next day was free from pain and had remained so until a few days before my advice was sought.

Hedley

ECCENTRICITY OF PUPILS DUE TO FAULTY POSITION OF HEAD AND EYES

By C. PRICE TANNER, L.R.C.P. LOND., M.R.C.S.

G. H. C.—aged eleven, was admitted into the Worcester County and City Lunatic Asylum on March 1st, 1887, and died at the beginning of the present year. He was an idiot from birth. No abnormality of eyes was noted at the time of admission. During the last two years of his life the following condition was observed repeatedly. His head was always flexed on to his chest, and as a rule the eyes were closed. When he opened his eyes the distance between the edges of the lids did not exceed from one fourth to three-eighths of an inch. The eyes were directed downwards and

forwards. The lateral movements were apparently normal, perhaps a little restricted in range. There was no convergent or divergent squint. Vertical movement of the eyes was never observed. On raising the upper lid only the upper half of the cornea and iris was visible, and the iris was found to be unequally contracted, its opening although circular, being nearer the upper than the lower margin of the cornea. The lower part of the cornea could only be seen by depressing the lower eyelid. The iris reacted sluggishly to light, but the eccentricity of the pupil was always present. The same condition obtained in both eyes, and persisted after death, being distinctly visible, though to a slightly less degree sixty-six hours after death. I think it probable that the position of the iris was due to the faulty position of the head, coupled with the downward strabismus which would allow light to act only upon the upper part of the iris.

Powick, near Worcester.

HOSPITAL PRACTICE, BRITISH AND FOREIGN

Nella autem est alia pro certo nocendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI De Sed. et Caus. Morb., lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

CASE OF LACERATED WOUND OPENING THE AXILLA
SIMULATING A STAB.

(Under the care of Mr. HULKE.)

THAT in instances of injury particularly those which are attended with breach of continuity of the surface of the body, much assistance towards attaining a correct appreciation of the circumstances of the wound will frequently be derived from inspecting the patient's clothes is a truism recognised by all but very neglected by many. An examination of the clothes should be a matter of routine, at the earliest opportunity, and where it is probable that a case may become the subject of legal inquiry it can never wisely be omitted. The following is an example of its utility.

W. C.—aged twenty-seven, a carman, was admitted into Founder ward on Nov. 7th, 1892, with a wound two inches long, vertically dividing the integument and the deeper structures of the upper part of the anterior fold of the axilla and passing deeply downwards into this space. Its edges were slightly frayed and bruised, suggestive of the wound having been inflicted with a blunt knife. The patient himself, dazed and confused, had no distinct recollection of the way in which he had incurred the injury but those who brought him to the hospital said that he had fallen off a van and he had, it was thought, struck his left shoulder against the splinter bar. An inspection of his shirt confirmed this account. Widely stained by a large effusion of blood, the material of the shirt corresponding to the situation of the wound was found to be quite entire, thus conclusively disproving a stab. The wound was flushed with a mercuric perchloride solution, covered with a dry antiseptic dressing and the arm secured to the side. On Nov. 21st he was dismissed with the wound healed. Here, not improbably, the wound may have been inflicted by the blunt edge of the iron stud attached to the ends of the splinter bar for securing the traces, and the toughness of the material of the shirt prevented its being torn. Where, however, the impact of the body and the implement is very great, large pieces may be torn out of a garment and deeply buried in a wound, and this not merely in gunshot injuries, but in those resulting from the accidents of civil life. Thus a lad was admitted into the Middlesex Hospital with a lacerated wound in the floor of the right axilla, he was said to have spiked himself on a piling in falling from a window on to the pavement. A few days later an abscess formed on the shoulder which enclosed a rag of linen nearly as large as the palm. This was found to be a piece of his shirt, the presence of which in the wound might

have been suspected previously had his clothes been examined when he was received into the hospital. Another and yet more striking illustration is the following. A gate-keeper at a railway crossing was struck down by an engine, which was slowly moving, and carried along for several yards before he could be extricated. The iron guard placed in front of the forewheel for the purpose of throwing off obstacles on the metals of the line had pierced the front of his thigh just below the groin and nearly traversed the limb. The huge wound was dressed by local surgeons and the man sent into the hospital. Some days afterwards an abscess formed in the gluteal region, and from this was taken out the bottom of his pocket, enclosing some copper pence. The presence of this foreign body had till then been unsuspected.

MANCHESTER ROYAL INFIRMARY

A CASE OF MYELITIS SIMULATING HÆMATOMYELIA BY ITS SUDDEN ONSET, UNILATERAL ANALGESIA AND THERMO-ANÆSTHESIA, GREY MATTER CHIEFLY AFFECTED

(Under the care of Dr STEELL.)

THE following is the report of a case showing the almost instantaneous onset of paralysis which may occur in acute myelitis, and the occasional difficulty, if not impossibility, in diagnosing between spinal hemorrhage and acute myelitis (or acute softening). The onset of paralysis could scarcely have been more sudden and yet not a trace of hemorrhage was to be found on careful microscopical examination of the whole of the affected part of the spinal cord. For the notes and remarks on this case we are indebted to Dr R. T. Williamson, Medical Registrar.

F. K.—, aged thirteen, was admitted at the Manchester Royal Infirmary on Nov 30th, 1891. The patient's illness commenced sixteen days before admission. On the day on which her symptoms commenced she arose, as usual, about eight o'clock in the morning feeling quite well. She dressed herself, combed her hair and then went downstairs and commenced to wind up the window blinds. She wound up half of them, but on attempting to wind up the blind of the next window she found that she could not extend her arms. Both arms had become suddenly paralysed (just as they were on admission, according to the statement of the patient, who is a most intelligent girl). About one hour later the legs became weak and by the evening both were completely paralysed. There was no pain anywhere at first, but the day after the onset of the paralysis she began to suffer from pain between the shoulders. This was rather severe, continued about a week and then diminished. On the day of the onset of the paralysis there was retention of urine, and ever since that date there has been retention with dribbling and loss of control over the motions. The catheter has been used twice daily. There was no history of injury to the back, or any history of symptoms of congenital or acquired syphilis. Her previous health was very good. For two days before the onset of paralysis she had felt somewhat "chilly," but there had been no rigor. She had done her work as usual, and otherwise had felt quite well. No history could be obtained of any other symptoms whatsoever before the onset of paralysis.

Dec. 1st, 1891.—The patient is anæmic, is fairly well nourished, the temperature is subnormal. She is quite unable to stand. She is just able to flex at the hip and knee to a very slight extent on the left side, but is unable to perform any movement of the right leg. Both feet are dropped. The legs are flaccid, the muscles are flabby, there is knee-jerk, absent on left side, present but very feeble on the right. There is no ankle-clonus. The plantar reflexes are feeble. Abdominal and epigastric reflexes are absent. There is slight effusion into the right knee-joint. The patient lies on her back, with the arms slightly abducted at the shoulders, the elbows flexed and her forearms bent over the chest, the fingers are semi flexed and the hands lie within the palmar surfaces on the chest. The grasp is exceedingly feeble, almost absent. The patient is unable to perform any other movement of the fingers or thumbs. She is unable to flex or extend the wrist. Also she is unable to extend either arm at the elbow, but when the limbs are extended passively she can flex at the elbows, the biceps and supinator longus contracting quite well on each side. The forearm is in a position of semi pronation and the patient is unable to supinate except to a very slight extent.

She can abduct at each shoulder, the deltoids contracting quite well. She can also flex and extend and rotate inwards and outwards at the shoulders, but adduction is very feeble. She can extend the upper arms forwards in front of her chest and almost make the elbows meet, she can also place her arms above her head on the pillow, but the forearms remain strongly flexed on the upper arms in these movements. She can shrug her shoulders, the trapezius contracting quite well on each side. The chest is motionless and the breathing entirely diaphragmatic. There is retention of urine, with dribbling and loss of control over the motions. The patient is able to feel and localise the touch of a pin's head quite well all over the limbs and trunk. On the left leg and left side of the abdomen and chest as high as the seventh rib (in the nipple line) she is unable to distinguish between the touch with the head and the point of a pin. In this area a deep prick does not cause any pain, even when the pin is thrust deeply into the skin and allowed to remain there. It is simply felt as a tactile sensation. This area of analgesia encloses a little to the left of the middle line of the abdomen and chest. She is able to distinguish readily between the point and head of a pin, and a pin prick is exceedingly painful on the right leg and right side of the abdomen and chest below the seventh rib. Above the seventh rib sensation to pain and tactile impressions is normal on the chest and also on the face. On the arms a pin prick was sharper on the anterior part of the upper arm, on the radial border of the forearm, on the radial half of the hands (dorsal and palmar surfaces), and on the thumbs than on other parts. In the above-mentioned analgesic area on the left side she is unable to distinguish between a hot and cold test-tube. On the right leg and right side of the abdomen she is able to distinguish a hot and cold test-tube readily, above the third rib on the right side she is unable to distinguish them. On the anterior part of the upper arms and on the radial border of the forearms and radial side of the hands hot and cold test-tubes are readily distinguished, but not on other parts of the arms. Over the deltoids and on the face hot and cold test-tubes are distinguished readily. The patient can tell the position of the legs on passive movements. There is tenderness on percussion over the seventh cervical and first and second dorsal spines. She has also slight pain in the lower cervical region, but has more in the lumbar region. There is great hyperæsthesia and pain all over the right leg, but there is no pain in the arms or in the left leg.

There is no spinal curvature or any affection of the facial, ocular, or tongue muscles. The left palpebral fissure and the left pupil are larger than the right. Both pupils react to light and accommodation. The hearing is good. Ophthalmoscopic examination shows the fundi to be normal. The pulse is 64, irregular in force and rhythm. The apex of the heart is pushed up into the fourth space, and situated about half an inch outside the nipple line. Otherwise the cardiac dulness is normal, as also are the heart sounds and the lungs, liver and spleen. The urine is acid, and there are no albumen, no sugar and no pus.

Dec. 5th.—The patient can slightly flex at the hip and knee on both sides. The movements are better on the left side than on the right, the knee jerks are both present, there is no ankle clonus, the toes are dropped.

12th.—There are analgesia, hyperæsthesia and thermo-anæsthesia in the same areas as above noted.

On Dec. 6th the evening temperature was 101° (previously it had been above 99.2°). During the next week the morning temperatures were normal, but the evening temperatures were high, 101° to 101.6°. During the following week the temperature was irregular, high ones in the morning and evening and varying from 101 to 104°.

14th.—Headache, face flushed. Pulse 129.

16th.—There is a large amount of pus in the urine. The tongue is furred. Pulse 150. Evening temperature 105°.

18th.—Patient drowsy. Rhonchial fremitus was felt, and riles and rhonchi were heard over both sides of the chest in front. Respiration 48, pulse 138.

22nd.—A rose coloured spot, resembling a typhoid spot, is seen on the abdomen, the abdomen is tympanitic, there is no diarrhoea, but the patient is under the influence of morphia; the tongue is dry and brown in the centre.

23rd.—The patient is troubled with a short, feeble, rattling cough, sputum is not expelled. She has great pain in the back in the right leg and right side of the abdomen. The spleen is a little enlarged and is felt below the ribs. Respiration 36, pulse 129. The patient is very drowsy. The temperature which had been falling for three days was 99° on the evening of the 23rd, and did not exceed 99 until Dec. 26th,

when it rose to 100.8 in the evening. The patient became very restless and excited, and died early in the morning of the 27th.

Necropsy.—The spinal meninges were normal. The spinal cord was soft in the lower cervical regions, firm at other parts, normal externally. On section the lower cervical region was soft, especially the grey matter. There were no signs of hemorrhage or of tumour growth, there was no abnormality of the vertebral canal. The pleural, pericardial and peritoneal cavities were normal. The heart, liver, kidneys and stomach presented no noteworthy appearances. The spleen weighed two ounces. There was extensive broncho-pneumonia of the left lung. The intestines were carefully examined, but only two small ulcers could be found. These were situated in the lower portion of the ileum, they were oval in shape, the long axis being parallel to the lumen of the intestine, and were situated on the side opposite to the mesenteric attachment, their edges were slightly raised. The ulcers and the mucous membrane around them for about half an inch were much congested. There was no perforation of the intestine and no blood in the intestinal canal. The spinal cord was hardened in Müller's fluid, embedded in celloidin, and sections were stained with aniline blue-black, logwood, osmic acid, and according to Weigert's method. The whole of the part of the cord affected by myelitis was cut into sections and carefully examined.

Microscopical examination revealed acute myelitis affecting the grey matter chiefly. The myelitis was limited to the lower half of the cervical region and the upper dorsal region (about the upper two-fifths). In the affected parts of grey matter the fine nerve fibres and ganglion cells were completely absent. The normal structure of the grey matter was replaced by cell infiltration and dilated bloodvessels. The cells were small and round, the size of leucocytes, with numerous very large compound granular cells—fat granular

around the left. In some of the sections the myelitis extended quite close to the antero-lateral ascending tract of Gowers on the right side, the anterior thirds of the white matter of the posterior median and posterior external columns on the left side were destroyed by myelitis at this level (Fig. 3). There was also a small area of myelitis in the crossed pyramidal tract of the left side along the course of a small vessel. Sections a little lower showed that the myelitis was mainly limited to the anterior horn on the right side, whilst on the left side the changes were the same as in Fig. 3. There was likewise a small area of myelitis in the right crossed pyramidal tract, in the upper dorsal region the myelitis became limited to the anterior horns and to the white matter just around, in some sections it was more marked on the left side, in others on the right, finally it became limited to the median half of each anterior horn and then disappeared. The lower three-fifths of the dorsal region and the whole of the lumbar region of the cord were normal. A number of sections were stained for micro-organisms according to Weigert's modification of Gram's method, and Loeffler's and Kühne's methods, but none were detected in the vessels or other parts, also in sections prepared according to Weigert's method for staining fibrin no stained matter could be detected in the small arteries.

Remarks by Dr. R. T. WILLIAMSON.—During life the case was looked upon as one of hematomyelia from the sudden onset of the symptoms. The affection of the bladder and rectum and the presence of analgesia proved that it was not simply one of acute anterior poliomyelitis. During the last twenty days of her life there were many symptoms pointing to typhoid fever, and her mother and a brother suffered from typhoid fever about the same time. The case shows that the suddenness of onset of the symptoms does not always enable us to separate spinal hemorrhage from all other organic diseases of the cord, except meningeal hemorrhage and hemorrhagic myelitis. The onset may

Area of myelitis shaded.

cells. The small vessels were very numerous, greatly dilated and filled with blood corpuscles. The nuclei of the capillaries were numerous. The walls of the smaller arteries were encrusted with leucocytes as were also the perivascular lymph sheaths of the vessels distended with them. In the parts of the white matter affected there was disappearance of nerve fibres and a similar cell infiltration with dilatation of bloodvessels. The changes were always most marked along the course of the vessels, especially around the commissural arteries and the anterior and mid cornual arteries. Where the myelitis was most marked—i.e. the lower part of the cervical region—the anterior median arteries were greatly dilated and surrounded by a thick coating of round cells. Careful examination failed to reveal the slightest hemorrhage or trace of old hemorrhage in any of the sections. The highest sections of the affected part (about the mid-cervical region) presented a small streak of myelitis (leucocytes, compound granular cells and dilated vessels) in each posterior horn of grey matter in the region of the posterior reticular formation (Fig. 1). There was also a great tendency for the posterior horns to break down in the sections, but the cell infiltration was limited to the parts just mentioned. The anterior third of each posterior median column presented slight ascending degenerative changes (increase of connective tissue and disappearance of nerve fibres). Fig. 2 represents the changes at a lower level, the myelitis extending slightly to the posterior external column on the left side. At a lower level the myelitis affected the grey matter extensively on both sides (anterior and posterior horns) but extended more posteriorly and was more marked in the posterior horn on the left side than on the right. Still lower (i.e. lowest part of cervical region) in addition to the changes just mentioned, the myelitis affected the white and grey commissures and extended into the white matter just around each anterior horn. The white matter was more affected around the right anterior horn than

be as sudden as in hematomyelia and yet examination of the cord may reveal myelitis only. Leyden has shown that pain is not a constant symptom in spinal hemorrhage and the case above recorded appears to furnish further evidence in favour of his statement that differential diagnosis between primary hemorrhage, secondary hemorrhage, and acute myelitis is sometimes impossible. It is not improbable that in some cases myelitis or spinal softening is due to thrombosis or embolism in the minute spinal vessels. It has long been known that occlusion of the small vessels of the cord by injection of inert powders into the circulation is followed by sudden paralysis and in the case above recorded the sudden onset of the symptoms strongly suggests as the initial lesion the occlusion of spinal vessels by a thrombus or by micro-organisms. As above mentioned, no thrombi or micro-organisms were detected in specially stained sections, but as only a comparatively few were treated in this way a small obstructed vessel might easily have escaped detection. The case is also interesting on account of the unilateral analgesia and thermo-anesthesia, whilst tactile sensation was retained. The sensory symptoms were those which have been regarded as characteristic of syringomyelia. Owing to the irregular distribution of the changes on both sides of the cord the case has not much bearing on the vexed questions of the path of conduction of painful impressions and the crossing of sensory fibres in the cord. One can say, however, that in this case of unilateral analgesia and thermo-anesthesia the lesion was one of the grey matter chiefly, and that the changes were most marked, and involved the posterior horn to a greater extent, on the analgesic side. On this side also the lesion extended at one spot to the anterior thirds of the columns of Goll and Burdach. In the lowest cervical and the upper dorsal regions the lesion of the anterior horn extended to the surrounding white matter on both sides.

DEVONSHIRE HOSPITAL, BUXTON

A CASE OF RAYNAUD'S DISEASE.

(Under the care of Mr ARTHUR SNIPTON.)

WHATEVER the exact pathology of Raynaud's disease may be there are now several cases recorded in which the disease appears to have commenced in consequence of injury. Dr Curtis¹ has described the case of a man aged twenty eight, who had received a severe blow in the abdomen from a capstan which was followed by gangrene of the lower extremities. The condition was diagnosed as due to sudden contusion of the solar plexus and splanchnic ganglia, which caused shock of the sympathetic system. Dr Pasteur² reported the case of a boy aged six, who had a number of attacks resembling Raynaud's disease after having been bitten in the leg by a dog. All these attacks commenced in the left hand. Anæmia and syphilis were predisposing causes in this case. A case is described by Dr Collier³ in which a purulent peritonitis, localised to the region of the solar plexus, had probably acted as the exciting cause. There are other cases recorded in which injury was apparently the starting point of the disease, as, for instance, one under the care of Lamotte—that of a man who received a blow from a stick on the arm and developed local asphyxia of the hand in consequence, but of the large number of examples of the disease published the proportion in which injury apparently started the mischief is small. We have published a series of articles on this subject in THE LANCET by Dr J. E. Morgan⁴ in which the disease is fully discussed and to this, and the contribution of Dr Barlow to the New Sydenham Society, we would refer our readers. It would be more satisfactory if the full account of this patient could be given on some future occasion, for the disease had nowhere extended beyond the second or asphyxial stage of Raynaud and in its nature it is progressive. For the notes of this case we are indebted to Mr H. Lloyd Davies, house surgeon.

J. H.—aged fifty seven, a carter, was admitted into the Devonshire Hospital, Buxton Nov. 2nd, 1892, with the following history. He had always been a healthy man until Oct. 5th last. On that day, whilst at his work, a mass of lime fell from a height on to him, knocking him down and partially burying him. He lay insensible for some time, but on regaining consciousness he was able after a while to walk home, though with great difficulty. Next morning he was unable to get up and go to his work owing to extreme weakness. From that time up to his admission the symptoms described below made themselves manifest. The following were more or less constantly present: Diminished surface temperature, with weakness of the extremities, inability to move the toes or to flex the fingers of the right hand upon the palm, and lividity of the ears. There was anæsthesia of these parts, extending in the case of the left arm to the middle of the forearm, in the right to about two inches above the wrist, in the legs it extended nearly up to the knee. The patient could feel the point of a needle when deeply inserted, but this gave rise to no pain. Other symptoms manifested themselves at intervals, generally about twice a day, viz. Extreme lividity of the ears, lividity of the nose and of the dorsal aspect of both hands, in the case of the right extending to the middle of the forearm, in the left to two inches above the wrist. A small area, about three inches in diameter, over the left shoulder became similarly affected. The lower extremities did not reach this asphyxiated condition, but became paler and colder. In all the affected parts during the exacerbations there was a sensation of numbness and of extreme cold. This condition lasted for a varying interval, and when passing off was accompanied by a sensation of heat, tingling and severe pain. At times the patient complained of giddiness and of feeling as he expressed it, "as if he were drunk." The symptoms varied a great deal in severity on different days. There was great mental depression, but the patient was a well developed, strong looking man and otherwise healthy.

Remarks by Mr LLOYD DAVIES.—I think that this case is interesting enough to be reported for the following reasons—the comparative rarity of the disease, the fact that it occurred in an elderly and previously healthy individual, and the peculiar nature of the exciting cause.

Medical Societies.

CLINICAL SOCIETY OF LONDON

Rhinoliths—Tophi in Inherited Gout at an Early Age—Uratic Deposits in the Conjunctival Membrane—Subphrenic Abscess in connexion with Perforating Gastric Ulcer

An ordinary meeting of this Society was held on Jan. 13th, the President, Sir Dyce Duckworth, in the chair.

Dr DE HAVILLAND HALL read a paper on a case of Rhinolith. The patient, a young lady aged sixteen, had suffered from a fetid discharge from the left nostril since the age of two and a half years. The left nostril was found to be almost completely occluded by a mass of stony hardness, the bulk being in the inferior meatus, but projections extended into the middle meatus. After several sittings the stone was removed piecemeal by means of the forceps. The largest piece was noosed by a wire loop and forcibly dragged out. The application of a 20 per cent. solution of cocaine much facilitated the removal. After washing and drying the fragments were found to weigh 92 grains. A chemical examination made by Dr Wilson Hake showed that the stone consisted of organic matter 28.4 and calcium phosphate 73.6 per cent. No nucleus was detected. Dr Hall remarked on the comparative rarity of rhinoliths. No specimen had previously been exhibited at the Clinical Society, and only four examples were shown at the Pathological Society. There are two specimens in the museum of University College Hospital and one each in the museums of St. Bartholomew's, Guy's, London and Westminster Hospitals respectively. In the museums of the Royal College of Surgeons and of the other hospitals with medical schools there were no specimens. He referred to an excellent monograph by Dr Max Sellmann of Carlsruhe, who had made a collection of all the pertinent literature, embracing a record of 110 cases, besides a few others of which he was unable to obtain full details. He concluded by giving the references of fifteen additional cases. The PRESIDENT asked what was the relation between the formation of rhinoliths and the occurrence of ozæna.—Mr PARKER remarked that the rhinolith, if pushed backwards, would not find its way into the larynx, but would probably drop into the œsophagus.—Mr W. G. SPENCER asked whether any special changes in the secretion of the mucous membrane of the nose had been found in connexion with these concretions and whether it was known what induced the precipitation of the phosphate of lime. Was there any difference in the reaction of the discharge?—Dr SOLOMON SMITH inquired if there was any objection to hanging the patient's head on the edge of the table, which would quite obviate the danger of a fragment when pushed back falling into the larynx.—The PRESIDENT asked if Dr Hall agreed with Dr Sellmann's proposition that vigorous blowing of the nose prevented the formation of rhinoliths.—Dr DE HAVILLAND HALL, in reply, said that if by ozæna was meant atrophic rhinitis that condition was probably inimical to the formation of rhinoliths because it increased the size of the nasal cavities, but the mere presence of rhinoliths would give rise to a fetid discharge. He thought himself that there was something in Dr Sellmann's suggestion that the feeble blowing of the nose common with women predisposed to the formation of concretions in that sex, but it must also be remembered that their formation was common in early life, when this difference in habit had probably not developed.

Sir DYCE DUCKWORTH read a paper on a case of Inherited Gout with production of Tophi at an Early Age. The patient, aged eighteen, a baker, came into St. Bartholomew's Hospital suffering from subacute gout in the hands and feet. He had had occasional attacks in the feet for nine years. There was a history of gout in his family. The patient was an ill developed youth with a small head. On both ears were numerous tophi, proved by chemical examination to consist of urates. The urine was of low specific gravity and contained a trace of albumen. There were no signs of cardiovascular degeneration or of lead impregnation. The case was considered to be one of inherited gout in spite of the negative history on this point. The patient was a total abstemious from alcoholic drinks and had certainly not been exposed to habits of luxury. Tophi at so early an age were known to be most rare, and no case of a like kind had come under Sir

⁴ *Ibid.* vol. II. 1889 p. 6 et seq.

Alfred Garrod's or his own notice. The case was believed to be one of atonic or cachectic gout associated with inadequate renal efficiency. A coloured drawing of the case was exhibited. Under treatment the active gouty symptoms subsided and the patient improved considerably in his general health.

Sir DYCE DUCKWORTH likewise communicated a paper by Mr. Davies Price of Nottingham on a case of Uric Deposits in the Conjunctival Mucous Membrane. The patient was a man aged seventy three, who had worked as a postboy, a cabman and a publican. There were numerous gouty deposits in and around the various joints of the body. These were, however, especially well marked in the phalangeal and metacarpo-phalangeal joints of both hands. Tophi were present in both ears. The general health was fairly good, with the exception of occasional attacks of acute gout. The history was one of alcohol and exposure. The family history was good and as far as could be ascertained free from gout. The condition of the conjunctival membrane of both eyes was very interesting, there being distinct chalky deposits on both sides. These uric deposits were for the most part arranged in small particles around and along the course of small blood vessels and their branches. The caruncula of each eye was also the seat of small deposits of gouty matter. The cornea was not invaded. There was no retinal change. A small portion taken from the conjunctival membrane gave the usual urexid reaction.—Dr. HADDEN inquired what was the earliest age at which true articular gout had been seen in children. He had not systematically examined the joints in all the necropsies he had made, but the youngest subject in whom he had found a deposit in the great-toe joint was aged twenty.—Dr. WILBERFORCE SMITH asked what were the President's reasons for believing that the kidneys were the seat of early granular change. Uric acid was only one of the factors which went to produce gout, a faulty condition of vessels was certainly also concerned in it. He thought that he had seen cases in which there were conjunctival spicules suggestive of uric deposits.—Dr. LONGMORE thought it not unlikely that gout might occur early in the children of gouty parents if they lived under unhealthy conditions.—The PRESIDENT said that he believed that his case was the earliest in which the presence of tophi had been chemically demonstrated. He condemned the study of gout from the pathological rather than from the clinical side. He thought that symptoms of gout were not rare at seven or eight years of age, and occurred in young women more frequently than was suspected. The patient's urine was of low specific gravity and contained a small quantity of albumen and the pulse was rather intermittent and irregular. The occurrence of conjunctival deposits seemed to be much rarer than the literature of the subject would lead one to believe.

Dr. F. G. PENROSE and LEE DICKINSON related cases of Abscess beneath the Diaphragm in connexion with Perforating Gastric Ulcer. They based their paper upon the notes of ten cases in which perforation of the stomach had resulted in the formation of an abscess confined within tolerably constant limits, to the upper part of the abdominal cavity. After referring briefly to the literature of the subject they showed that the ordinary physical signs of pneumothorax might be present, but not in the position usual to that condition. Most of the cases gave hyper resonance on percussion, amphoric breathing and the bell note over an area more or less confined to the epigastrium and the left hypochondrium. There was generally evidence of compression, either with or without pleural effusion, at the base of the left lung behind. The heart's apex was generally to a slight extent displaced. Sounds indistinguishable from pericardial or pleuritic friction, or both, were at times detected in some of the cases. The diagnosis of the cases was usually not difficult but certain thoracic complications, such as empyema, pyo-pneumothorax or pulmonary abscess, were liable to arise and might be very misleading. The limits of the cavity were found to be fairly constant and as follows. Above, the arch of the diaphragm, on the right, the falciform ligament of the liver, in front, the anterior abdominal wall, behind and below the left lobe, being adherent to the anterior abdominal wall and thus closing the abscess cavity at its anterior inferior angle, on the left the cardiac end of the stomach, the spleen and the diaphragm, there being a deep pocket of the abscess extending backwards between these organs. They stated that they had brought the cases before the Society in the hope that the surgical treatment would be discussed. They asked for information on the two following points especially

(a) How the deep pocket of the abscess in the direction of the spleen should be drained, and (b) whether it would be feasible to close the hole in the stomach wall at the same time that the operation for the relief of the abscess was undertaken.—Mr. WASHINGTON HAWARD referred to the case of a young woman aged twenty six who was brought into St. George's Hospital in a state of collapse from the perforation of a gastric ulcer in which immediate operation was undertaken and the patient was still alive though not well. The patient had suffered from long continued dyspepsia with some pain, but there were no hæmatemesis and no acute symptoms, till one evening immediately after food, when pain supervened, increasing in the course of the night. The abdomen was opened in the mid line at the upper part, and fluid and gas escaped, together with gastric contents. At the posterior surface of the stomach, at the larger end, an ulcer was found large enough to admit a forefinger. This could not be excised owing to the great inflammatory infiltration of the gastric wall. He therefore attached the aperture in the stomach to the abdominal wall and inserted a drainage-tube. A year previously he was operating on a case which had perforated some time before when he mistook the membrane lining the abscess for the gastric wall and attached the former to the wall of the abdomen, the patient sank and died two days later. In the case he first described, on the third or fourth day an acute suppurative parotitis developed which was of non pyæmic character. He thought that the leakage in most of the cases was gradual, setting up a limiting peritonitis. The difficulty of dealing with a gastric ulcer was much greater when the interference came at a late stage of the disease. A great danger was the imperfect drainage of the cavity, for this it would be wise to make a counter incision in the loin whenever practicable.—Mr. W. G. SPENCER mentioned a case he had seen in the Westminster Hospital, under the care of Dr. Sturges. A fluctuating swelling formed over the cartilages of the false ribs on the left side, and there was impulse on coughing. It was opened to the left of the mid line and a sinus tracked obliquely downwards to a large cavity in the region of the spleen. It drained well and ultimately healed. The best incision was one immediately beneath the sternum, for it admitted of good drainage and was less liable to open the general peritoneal cavity. A case he had seen under Dr. Hall seemed to suggest that cure had been brought about by the abscess discharging itself into the stomach or intestine.—Dr. SAMUEL WEST could not feel at all sure that the localisation of the abscess was so constant as had been suggested by Drs. Penrose and Lee Dickinson, he had certainly seen it pass over the liver presenting in the right front. As to the diagnosis, it was often a matter of great difficulty, there might be signs of pus in some part of the body and the indications might be that it was abdominal, but he quoted a case in which the symptoms became entirely thoracic, though the case turned out to be one of gastric ulcer with abdominal abscess after all. He remarked on the curious latency of the symptoms in some cases of gastric ulcer—indeed a number of them presented no symptoms at all. The diagnosis as to the cause of the local peritonitis might be made wrongly. A patient was admitted with typical symptoms of gastric ulcer followed by peritonitis. At the necropsy it was found that the perforation was of an ulcer of doubtful nature in the small intestine. There was a gastric ulcer present but that was not the cause of the mischief. He was a little sceptical of the feasibility of the surgical closing of these ulcers on account of their seat, their adhesions to the parts around and the condition of the gastric wall in the neighbourhood. He referred to another case in which a perforated gastric ulcer led to the formation of an abscess of enormous extent, reaching down nearly to the pelvis.—Mr. PEARCE GOULD referred to a paper by Dr. Coupland on this subject, and in one of the cases there recorded the abscess was on the right side, and it was so with another instance related by Leyden of Berlin. In the above paper there were particulars of a youth aged fifteen who presented the signs of an abdominal abscess on the right side. There was a tympanic area reaching up as high as the fifth interspace in the axilla and nearly obliterating the liver dulness. The temperature was high. He cut down and opened the abscess below the twelfth rib draining it from the loin, with a successful result. In another case of a woman aged thirty six there was a history of gastric ulcer then there was an onset of severe symptoms left pleurisy with effusion and a prominence appeared in the epigastrium, over this there was a tympanic note. He opened it in front, let out pus and gas and then excised a piece of the tenth rib

and drained it from behind. The patient died and at the necropsy another abscess was found in the base of the left lung. These cases were extremely grave, a successful issue being very rare, and their gravity depended to a great extent on the complicated nature of the cavity. As the pus lay usually behind the intestines, unless it were dealt with early and opened at a dependent point the prospect was not a brilliant one. In some cases better drainage would be obtained by turning the patient over on to his face. The abscess had a great tendency to spread upwards through the diaphragm.—Dr LEE DICKINSON, in reply, said that all the cases he had related were on the left side and strictly bounded by the falciform ligament. The cases he had read of on the right side were not associated with gastric ulcer. He did not admit that the diagnosis was so difficult as had been considered. In an anemic woman a sudden attack of peritonitis almost certainly indicated gastric ulcer which had perforated, and the only treatment promising success was immediate laparotomy, and many cases had revived in an encouraging manner under this method. Cases of this nature had been reported by Dr Sinclair of Manchester and by Mr Taylor of Birmingham. He related, in conclusion, a case in which it was believed that an abscess had formed without perforation of a gastric ulcer

PATHOLOGICAL SOCIETY OF LONDON

Multiple Papillomata of the Colon and Rectum—Cancers of Various Organs and Non-cancerous Mammary Cysts due to Psorosperms—Blood Tumour in a case of Haemophilia

AN ordinary meeting of this Society was held on Jan 17th, the President, Sir George Humphry, in the chair.

Dr NORMAN DALTON showed specimens of Multiple Papillomata of the Colon and Rectum. The case was that of a woman aged twenty eight, under the care of Professor William Rose in King's College Hospital. She had suffered from pain and from the discharge of blood and mucus from the rectum for about two years. Shortly before death a number of polypi were removed from the rectum, but the bleeding continued and proved fatal. At the post mortem examination the only lesions were in the large intestine and rectum. The bowel contained a good deal of blood. In the rectum there was a ragged area from which the tumours had been removed during life, but a few tumours remained, and there were others in the colon and a large group of them in the caecum. Each polypus consisted of a stalk which varied in length from two inches and a half downwards and was rounded in some cases and flat in others. Nearly all the stalks expanded at their free ends, some being bulbous and others like a fringe. These extremities were mostly soft and bleeding. Microscopically the stalk consisted of fibrous tissue and bloodvessels covered by normal mucous membrane, and the extremity of the same elements except that in some polypi there was a certain amount of glandular proliferation in this position. Microscopical examination of the base of the stalk showed that the tumours were simple outgrowths of the mucous membrane, there being no infiltration of the muscular coat. The recorded cases of multiple polypi of the large intestine and rectum showed that the growths were partly adenomata and partly papillomata, in fact, the tumours were outgrowths of the submucous tissue and mucous membrane and contained the elements of those tissues (i.e., connective tissue, bloodvessels and glands) in varying proportions. In the analogous villous tumour of the bladder the glandular element was practically omitted because the bladder mucous membrane was not rich in glands like that of the intestine. These tumours were not strictly speaking malignant, but cases had been brought forward which showed that occasionally they become so, infiltrating the muscular coat and reproducing themselves in other organs. In the same way the true ovarian cystoma, which was usually not malignant, might get into the peritoneum and produce a rapidly fatal form of cancer. The immediate cause of the development of so many polypi in the colon and rectum might be parasitic, but there was probably a congenital predisposition to their growth, as Mr Harrison Cripps had reported three cases which occurred in one family. Lastly, it was curious that these polypi, which so much resembled enormously hypertrophied villi, should occur in such numbers only on surfaces where there were normally no villi—i.e., on the mucous membranes of the large intestine and rectum of the bladder and of the uterus. He therefore suggested the possibility that one factor in their growth might be some developmental mistake, which, from some

cause or other, became continuous in after life.—Mr D'ARBY POWDER inquired if in the case shown there was a history of heredity.—Mr JONATHAN HUTCHINSON, jun., had seen two or three instances, and in one he operated and removed large numbers of polypi. Microscopically they were all adenomata. A case under Mr Treves of a patient aged twenty exhibited at the necropsy multiple polypi and numerous epitheliomatous ulcers side by side.—Mr STEPHEN PAGET mentioned the case of a youth aged seventeen who had been under the care of Mr Thomas Smith with multiple polypi and who ultimately died of hæmorrhage. The patient had two sisters suffering from the same disease, one of whom afterwards died, and cancer of the bowel, degenerating into colloid, was found.—Mr MAKINS referred to an instance in a girl of eighteen, and several polypi were removed. Two years later she returned with intestinal obstruction which proved fatal, and post mortem well marked columnar epitheloma was found.—Dr DALTON, in reply, said he was unable to ascertain anything as to the family history of the patient.

Mr J JACKSON CLARKE, who showed moist specimens, microscopic preparations and drawings, referred to his last communication to the Society (Dec 20th, 1892) and said that further experience had strengthened his conviction that psorosperms caused cancer. He had found, besides the capsule which appeared to be secreted by the host cell, that the parasite, by a condensation of the outer layers of the ectosarc, sometimes possessed a proper capsule, and this in some cases had the form of two concentric layers joined by radial bars. He had succeeded in finding the radial arrangement of protoplasm described by some other observers. In the cancer of the bladder secondary to one of the cervix uteri he had observed that the sporing took place in the centre of the new formed epithelial tubes and that the plasmodia and spores made their way between the epithelial cells into the supporting connective tissue, where they could be observed to have digested portions of fibres and cells. Spore formation did not always occur simultaneously throughout the ripe psorosperm, sometimes it began at the periphery or at the centre. In the latter case the spores might be mistaken for phagocytes. A cystic non-cancerous breast removed by Mr Edmund Owen from a lady aged fifty showed on examination that many of the epithelial cells lining the cysts contained large amoeboid psorosperms, while the cyst contents were made up of plasmodia and psorosperms with some fat globules and crystals. In another cystic breast, also removed by Mr Edmund Owen and similar to the one referred to, but complicated by commencing scirrhus cancer, the contents of the cyst, placed on the warm stage immediately after removal, exhibited active movement. A duct papilloma of the breast, removed by Mr Pepper from a girl aged fourteen, contained multitudes of psorosperms. An adenoma of the kidney also contained the parasites, chiefly in the amoeboid stage. In an encapsuled adenoma of the thyroid gland and two adenocarcinomata of the testes, psorosperms, chiefly in the plasmodial forms, had been observed by him (Mr Clarke) in every part of the growth. He had examined round celled, myeloid and melanotic sarcomas and found in them all absolutely overwhelming evidence of their being caused by psorosperms. Around the bloodvessels actively budding were numbers of free amoeboid and intra cellular parasites. The former clustered thickly around the new growing shoots of the bloodvessels. In the inter vascular areas were immense numbers of the parasites in the condensed highly refracting stage, and the same process of reticulation and spore formation he had described in cancers could be traced with the greatest ease in all the sarcomas examined. He insisted on the ease with which these "ripe" psorosperms could be recognised by focussing a little above the section, when their high refracting power caused them to appear as bright globes comparable to Darier's "grains." More than two thirds of the weight of a round celled sarcoma of the testis was accounted for by the psorosperms present. He computed that on an average at least one third of the weight of every one of twenty different cancers (skin, nasal septum, tongue, cornea, breast, uterus, bladder &c.) was accounted for by the parasites they contained.—Mr W G SPENCE referred to the microscopic specimens, in which he had been unable to recognise the characteristics which were held to distinguish them. It was true that Metchnikoff had pointed out that psorospermiosis in rabbits was associated with small celled proliferation but it did not follow from this that proliferation of itself was indicative of tumour formation. He instanced the proliferation of the ciliated

epithelium lining the central canal of the spinal cord, which was a common occurrence, but had nothing to do with the formation of new growths. He thought that most of the changes shown were cell alterations produced in the preparation.—Dr GALLOWAY said that it was at his request that Mr Clarke had brought up the subject again, his views being more matured. Supposing that it were taken for granted that the structures exhibited were psorosperms, he thought it was not shown that they went through the stages which were known to mark the development of psorosperms. The very name was unfortunate, as it was used by various writers in very different senses. He suggested that "protozoa" was a better word and less open to criticism. He did not think the specimens which had been shown could justly be compared with undoubted examples of psorosperms that had been previously exhibited. Even supposing the deductions were so far correct, it was not justifiable to go further and say without experiment that these organisms were the cause of cancer.—Mr D'ARCY POWER complained that the drawings did not represent what he saw under the microscope. The power used was very high and the mode of preparation new as applied to epithelium, and he maintained that it was scarcely as yet known what appearance normal epithelium would present under these conditions.—Dr G S WOODHEAD thought that Mr Clarke's postulates were a little in advance of the views that at present commanded acceptance, but he felt that Mr Spencer had gone too far when he attributed all the appearances to alterations artificially produced in the cells. He himself had studied a very large number of sections prepared by different observers and they all showed something which was absolutely different to anything that could be found in ordinary epithelial cells, but these were demonstrated by methods of special preparation and staining. It was possible that these bodies might be the causal agents of cancer—indeed, there was a certain amount of presumptive evidence that they were so, they also appeared to be parasitic. Though he had examined very carefully, in no case had he seen anything resembling a spore, the nearest appearance to this was the separation of a nucleus into two parts. He pointed out that numerous observers thought they had found protozoa in new growths, but the great majority had returned to the conclusion that they were dealing with altered cells, except in the specimens of the more recent observers who had adopted special methods of preparation.—Mr EDGAR WILLETT asked if these bodies had been found in healthy muscle or other normal structures of the body.—Mr SHATTOCK said that he and Mr Ballance had strongly maintained that cancer was a parasitic disease and that the parasite was probably a protozoon, but further evidence was necessary before Mr Clarke's conclusions could be accepted and he felt that Koch's four postulates must be fulfilled. The line of research now required was to endeavour to complete the cycle of the parasite outside the body and cause infection of animals from the parasite so grown.—Mr J JACKSON CLARKE, in reply, said that he used the term "psorosperm" because of its indefiniteness. These organisms were perhaps more akin to the hæmatozoa such as could be obtained from the tortoise. He deprecated searching for special shapes of the organism in different animals, they probably varied in form under different conditions. As to the important cycle outside the body, he did not recognise its necessity. He regretted the retrograde step taken by Drs Ruffer and Walker when they abandoned the idea of spore formation. He defined a spore to be an amoeboid psorosperm, arising from a ripe psorosperm. He quoted several instances of successful inoculation of both cancer and sarcoma.—The PRESIDENT said they had been yearning for years to be able to attribute cancer to some vegetable or animal parasite. It appeared to him that two things remained to be done first, the true nature of these organisms required to be distinctly and positively ascertained, and, secondly, the real relations they bore to the production of cancer should be made out. It was a disappointment to him to find that Mr Clarke was able to demonstrate psorosperms in a variety of growths which were not cancerous. The specimens were referred to the Morbid Growths Committee, members of the Society were invited to bring other specimens for comparison and the secretaries were desired to arrange that this should be followed by a meeting convened especially for the discussion of the subject.

Mr MAKINS related the history of a case of Hæmophilia, in which an enormous blood tumour developed at the site of a wound at the anterior aspect of the shoulder. The patient died of internal hæmorrhage and exhaustion. The tumour

extended vertically from above the clavicle to the hollow of the forearm bent at right angles across the chest and laterally from the arm at the side of the chest to mid sternum. It was coarsely lobulated on the surface, greyish red in colour and very coherent, as it could be freely manipulated without causing any breach of surface. The whole tumour was developed during seventeen days. It consisted of laminated blood clot, with developing connective tissue in its interstices.

Mr MAKINS also exhibited a Meckel's Diverticulum, removed from a case of acute intestinal obstruction in a child. The diverticulum, extinguiser shaped in outline, was perforated with thirteen small openings so as to resemble a sieve. Some of the openings were beveled at the expense of the mucous coat, others were sharply cut. It was suggested that these ulcers might either be the result of ulceration in a diverticulum of a similar nature to that seen in perforating appendicitis, or that they might be mere spots of local gangrene due to tension.

Mr JONATHAN HUTCHINSON, jun., referred to a case of a wound of the thenar eminence in a man which bled severely and which required, ten days later, ligature of both radial and ulnar arteries. The incisions for these operations also oozed profusely and they then discovered that the patient was a "bleeder."

The following card specimens were shown —

Dr F C TURNER. Sarcoma of both Ovaries and of Peritoneum in a Child.

Dr H. D. ROLLESTON. Gummata in Heart Wall.

PROVINCIAL MEDICAL SOCIETIES

BRADFORD MEDICO CHIRURGICAL SOCIETY.—A meeting of this Society was held on Jan 10th, Dr J H. Bell, President, in the chair.—Dr MAJOR showed preparations from Epithelioma of the Tongue, Dr FIFTH Abscess of Lung after removal of Malignant Growth of the Tongue, and Dr RABAGLIATI a Large Ovarian Cyst.—Mr PETTITT showed a specimen from and read notes of a case of Obscure Perforation of Gastric Ulcer. A large cavity, formed by adhesion of the stomach to the diaphragm, communicated with the stomach through a gastric ulcer.—Dr KERR read a paper on Monocular Symptoms in Hysteria. In functional cases he remarked that the retina was not at fault and that the key to the position is found in Schweigger's statement that "amaurosis fugax is not real but imaginary." The observation by patients of a pin held first at reading distance, then nearer and again further off is a satisfactory and delicate test.—Mr G H. DODD introduced a wool warehouseman who had recovered from anthrax of the right cheek. His pulse reached 160 and his temperature 103.8°. Anthrax bacilli were found in the serum of vesicles. The pustule was freely excised and solid zinc chloride applied to the raw surface. Sections stained by Gram's method revealed bacilli in great numbers in the upper parts of the corium, and not extending in the skin beyond the areola.—Dr BELL said these cases were at one time common, but now rare from precautions taken.—Mr HORROCKS recorded a case which recovered spontaneously.—Drs Rabagliati, Kerr, Lodge, Arnold Evans and Mr Pettitt joined in the discussion.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting held on Jan 12th the following list of office bearers and of members of the Council and Pathological and Microscopical Committee was adopted.—President T R. Glynn, Vice-Presidents J Kellett Smith, E W Hope, James Armstrong* and Peter Davidson*, Hon. Treasurer J W Warburton, Hon. General Secretary W Macfie Campbell, Hon. Secretary to Ordinary Meetings G G Hamilton, Hon. Librarian T Bushby*, Council James Barr*, A O Harris, N E Roberts, C H. Shears, David Smart*, Henry Wilson, J M Chisholm*, T B Grimsdale*, Richmond Leigh*, Percy Marsh*, J Tawse Nisbet* and B J Phillips*. Microscopical and Pathological Committee J H. Abram, F H. Barendt*, A. Barron, T B Grimsdale, G G Hamilton, A. A. Kanthack*, F C Larkin, J R. Logan, R W Murray, F T Paul, W T Thomas and Joseph Wiglesworth. Auditors A O Harris* and A. Dunbar*. Those marked (*) did not hold the same office last year.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—This Society met on Jan 12th, Dr J Adamson, Vice President, in the chair.—Dr D DRUMMOND showed (1) a man in whom the symptoms of Locomotor Ataxia had

developed at the age of sixty seven, (2) a girl with Ophthalmoplegia Externa, probably due to gumma situate in the sphenoidal fissure.—Dr ROBERTSON showed a man in whom he had excised the Drumhead and Ossicles on each side.—Dr LIMONT showed (1) the result of treatment by Resorcin in two cases of Favus, (2) a case of Sycois of twelve years' duration approaching cure.—Dr BRAMWELL showed Diseased Ovaries removed from a patient the subject of Friedreich's disease.—Mr WILLIAMSON showed Gangrenous Cæcum and Ascending Colon removed by operation from an acute case of Volvulus, and gave details of a number of his recent cases of abdominal section for intestinal obstruction.—Dr DRUMMOND showed an interesting specimen of Tumour of the Pons involving the Crus, the right third, fourth, fifth, sixth and seventh nerves and the left third nerve.—Dr PEROVAL showed (1) Permanent Preparations of Diseased Eyes, including one of Leucoma and Adherent Iris and two of Detachment of the Retina, (2) Pocket Test for Colour Blindness.—Dr MURPHY showed (1) Uterus and Fibroid successfully removed by an intra peritoneal method, (2) Ruptured Tube. Dr Murphy read a paper on the Importance of Early Operation in the Treatment of Intestinal Obstruction.

SHEFFIELD MEDICO CHIRURGICAL SOCIETY—This Society met on Dec. 22nd, 1892, the President, Mr Simeon Snell, in the chair. The following cases, notes and specimens came before the Society.—Dr COOKING exhibited two cases of Ataxia Paraplegia, both in married females, in neither of whom was there evidence of intra cranial disease or syphilis nor any neurotic family history or history of injury or exposure.—Dr PORTER read notes and showed photographs of two cases of Progressive Muscular Atrophy, in one of whom the disease commenced in the legs and in the other in the scapular muscles. He deprecated the tendency to multiply the types of this disease.—Dr WILKINSON read notes of a case of Acute Ulcerative Colitis, in which post mortem extensive and deep ulceration was found throughout the large intestine.—The PRESIDENT showed cases of Herpes Frontalis and Embolism of the Central Artery of the Retina, and read notes of a rare case of Associated Movement of the Eyelids.—Dr DAVY introduced a child with Hard Painless Tumour in the Left Epigastrium.—Mr RICHARD FAYELL exhibited an Ovarian Dermoid Cyst removed with safety during early pregnancy.—The following specimens were also shown: Descending Colon terminating in the Bladder, by Dr J. H. WILSON, Calcified Fibroid Polypus Uteri, Ulcer of Stomach, and Perforating Ulcer of the Duodenum, by Dr OWEN, Aneurysm of the Arch of the Aorta, rupturing into the Trachea, by Mr BROWNLOW.—The following gentlemen took part in the discussion: Drs Burgess, Stokes, Arthur Hall, Wilkinson, Clarke, Porter and Mills, and Messrs Jones and Coombe.—A meeting was held on Thursday, Jan. 12th, 1893, the President, Mr Simeon Snell, in the chair.—Mr SNELL introduced a young woman aged twenty-six suffering from Ophthalmoplegia Externa and Interna, with considerable proptosis. The palsy of the internal and external muscles was complete, the pupil being motionless and the accommodation lost. The cause of the proptosis was the loss of tension owing to the paralysed state of the recti and external muscles. There was no manifest history of syphilis.—Dr DYSON showed a case of Ataxia Paraplegia. There was a history of both syphilis and sexual excess. The man had suffered for twelve years, but the disease had got much worse during the last three months. The ataxia is present in both arms and in both legs.—Mr DALE JAMES brought forward a man suffering from Eczema of the Nails. When the patient first complained of this condition two years ago he was engaged in breaking up for firewood American bacon boxes loaded with salt and lard. There was a vesicular eruption on the hands for some months before the nails became affected.—Mr PYE-SMITH read notes of a case of Congenital Enlargement of the Thyroid Body. It occurred in a female child whose mother had suffered three and a half years previously from exophthalmic goitre and who still had an enlarged thyroid and slight proptosis. The enlargement gradually diminished without treatment and was scarcely perceptible at the end of a month, the head assuming its normal position.—Dr KERR related the notes of a case of Lymphadenosplenic Leucocytæmia. The patient was a man aged forty-five. Swellings in the groin and axillæ were first noticed seven months previously to his admission into hospital in August and he died in the beginning of November. The spleen extended nearly to the ilium and to the middle line. The blood showed a great excess of white corpuscles with diminution

of red. The symptoms returned after some improvement in an aggravated form, pneumonia supervened and the patient died. The histological change in the spleen and lymphatic glands was one of simple hyperplasia.—Dr MARTIN gave particulars of a case of Pelvic Cellulitis in which profuse diarrhoea ceased twenty-four hours after half-drachm doses of dermatol every four hours had been ordered.—Dr ARTHUR HALL read a short paper on Concussion of the Spine. He commenced by giving the notes of a patient (who had been shown earlier in the evening), a middle-aged woman addicted to drink. She had fallen down stairs in October, 1890, and one month later the symptoms of paralysis began in the arms and legs, which gradually increased until the paralysis was almost complete below the origin of the eighth cervical nerve. The patient improved very satisfactorily under rest, massage and large doses of iodide of potassium, with liquor hydargyri perchloridi, and she was now able to walk and perform her ordinary duties.—The following joined in the discussion: The President, Mr C. Atkin, Dr White, Mr Reckless and Dr Martin.

YORK MEDICAL SOCIETY—At a meeting of this Society for a discussion on Treatment by Suggestion, Dr Petch, President, in the chair, Dr MILNE BRAMWELL, in dealing with this subject, considered in the first place its therapeutic uses. Of these the works of Bernheim and others, he said, afford satisfactory evidence. He then cited illustrations from his (Dr Bramwell's) own practice, of which the following are condensed notes: Dipomania, seventeen years' duration, treated nearly three years ago, no relapse, chronic hyperidrosis, treated three years ago, no relapse, hysterical aphonia, of four years' duration, rapidly cured, pruritis vulvæ and eczema associated with chronic constipation cured by suggestion over three years ago after failure of medical treatment, no relapse. Reference was then made to the experience of Dr Esdaile, who largely employed hypnotism as an anæsthetic in Calcutta just before the introduction of chloroform. Cases had frequently occurred in his own practice where it had successfully replaced chloroform or ether. Regarding susceptibility to hypnosis, Dr Bramwell's personal results differed but little from those of Bernheim, Liébeault, Wetterstrand, Moll and Bénéus—the percentage of success being as great and the difficulties encountered much the same. The dangers of hypnosis were regarded as mainly theoretical. Cases had not yet been published in which hypnotism has been proved to do harm. Liébeault, with his thirty years' experience, and Bernheim in 15,000 cases had never observed bad effects. In no instance had Dr Bramwell seen evil results from hypnotism. His patients passed into a state of drowsiness and lethargy more or less profound, with or without partial or complete loss of memory of what had occurred during hypnosis, and with more or less complete anæsthesia during that condition. All else was the result of suggestion made during hypnosis. Efficient safeguards rendered, he said, improper influence or interference with will power impossible.—Dr KINGSBURY divided the dangers of hypnotism into those of mind, body and morals. As to the mental dangers, it had been recklessly asserted by many that hypnotic treatment produced instability of mind, but so far no proof of this had been offered. As to physical dangers, Dr Kingsbury had no knowledge of any. The moral dangers, however, could not be disposed of so flippantly. He thought they had been greatly exaggerated. He advised his hearers, however, never to hypnotise a woman except in the presence of a witness, and never to hypnotise except for therapeutic purposes.—Dr RABAGLIATI, Dr MEYERS, Dr YELLOWLEES and others advocated the investigation of hypnotism as a remedial agent and gave evidence from their own experience of successful results in cases treated by "suggestion."

ROYAL COLLEGE OF SURGEONS IN IRELAND
FELLOWSHIP EXAMINATION.—Mr Alexander Lane, M.R.C.S., having passed the necessary examination, has been admitted a Fellow of the College.

MEDICAL DEFENCE UNION, LIMITED—A Council meeting was held at 429 Strand, London, on Jan. 12th. Dr Purcell in the chair, when twenty-nine new members were accepted and various matters affecting the future conduct of the business of the company, including the presidency, the offices and the secretarial work, were referred to a committee with instructions to report thereon.

Rebels and Notices of Books.

The Structure and Functions of the Brain and Spinal Cord
By VICTOR HORSLEY, B.S., F.R.C.S., F.R.S. London
Charles Griffin and Co., Limited. 1892.

IN this volume are reproduced the Fullman lectures delivered by Professor Horsley at the Royal Institution in 1891. They are not designed, we are informed, as a monograph on the subject, but merely to furnish an elementary sketch of it. It is a pity, we think, that the scope of the present volume is not as clearly indicated in the title as it is in the preface. The former scarcely prepares the reader for the statement given in the latter that the present volume discusses the spinal cord and ganglia alone. The first lecture is historical and interesting, tracing as it does the successive steps by which our knowledge of nervous structures and their function has been gradually built up, from the crude ideas of Plato and Aristotle to the epoch-making experiments of Fritsch and Hitzig. Then follow lectures devoted to a description of the nervous systems of the lower forms of life, the simplest being taken first and then in turn those of gradually increasing complexity. The last six lectures—there are nine in all—are devoted to the spinal cord and nerve fibres in the Vertebrata. These are considered from the anatomical and physiological point of view, and many of the experiments which have marked advances in our knowledge are described clearly and graphically, so that the reader has not only the knowledge presented to him, but, what makes it all the more interesting, is shown the various phases through which it has passed in the process of growth to its present form.

The subject-matter, as will be seen, is interesting and the lectures as such must have been admirable. In spite of the numerous illustrations in this volume we miss the blackboard and the pointer, and this loss obtrudes itself all the more because the lectures are cast apparently in almost the very words in which they were delivered. They suffer, in short, from the disadvantage which all printed lectures must have, but more especially those which have been so abundantly illustrated as to have been almost of the nature of demonstrations. When we have said this, and that the occasionally somewhat slipshod language of the platform has now and then crept into type, we have said the little that can be said in disparagement of a most interesting volume.

Guide to the Science of Photo-micrography. Second Edition.
Entirely rewritten and much enlarged. By EDWARD C. BOUSFIELD, L.R.C.P. Lond. London J & A. Churchill. 1892.

IN no department of applied science are close attention to detail, careful observation, and patient application more necessary than in photo-micrography. At one time every amateur photographer with a slight knowledge of the use of the microscope looked upon photo-micrography as something to be lightly taken up and easily mastered, and many were the instructions that issued from such amateurs. Now, however, we have passed through that stage and most of us are willing to learn from any of the very few men who have made themselves thorough masters of this fascinating work. Amongst these Mr. Bousfield must take a high position, and all photo-micrographers will receive with pleasure the intimation that his book has passed into a second edition. Here we can trace a master hand, and a careful perusal of these pages will enable the long suffering micro-photographer to see where he has been going astray for months, the arrangement of his condenser, of his screens, of his light and of his object may one or all have been wrong, if so here he will find information as to the best way of putting any of

them right. As might be expected, most of the objects taken as examples on which to work are those met with in the biological or the pathological laboratory, and for this reason the information given and the advice tendered are for a wider clientele than is usually the case with works of this kind. After descanting on the advantages of photo-micrographic reproduction, Mr. Bousfield describes first the general photographic accessories. This is followed by a detailed account of photo-micrographic cameras and stands, after which he deals with the optical apparatus required—objectives, oculars, condensers &c.—with illumination, and then with special technique, exposure and development, following these up with a series of chapters on the photography of interesting objects, including bacteria and the like. Photo-modelling is also dealt with, as also the production of positives, lantern slide making, copying, enlarging, and lastly the photography of cultures of bacteria in test-tubes, with which he has been very successful. But, after all, "the proof o' the puddin's the preening o' it," as the Scotch say, and the samples we have of Mr. Bousfield's photographs on the frontispiece are so excellent that we can scarcely imagine anything better in the way of photo-micrographs, they are certainly equal to any reproductions that we have yet seen, and could only be obtained from very fine negatives. It is rather a curious fact, however, that although the use of the pyro-developer (Pringle's "1-2-3") is recommended throughout the book the examples given have without exception been developed with hydro-quinone, which seems to prove that in the hands of an expert any good developer may give first-class results.

As a practical manual this work will take its place by, and form a supplement to, the few other good works on photo-micrography already published in English.

Malignant Disease of the Throat and Nose. By DAVID NEWMAN, M.D. Edinburgh and London Young & Pentland. 1892.

EVERY item of information, especially from the clinical side, that can be given in the class of disease discussed in this book is of extreme value. Dr. Newman has had exceptionally good opportunities for collecting his evidence, and his writings are generally thoughtful, his reasoning logical, and his diction correct. The work now under observation is essentially clinical—a point to which exception can scarcely be taken, as the value of an author's statements can then be accurately gauged. But in Dr. Newman's latest work there are portions in which we wish he had been a little more systematic. Thus of fifty cases of malignant disease of the larynx observed by him we are given particulars of only eight, and we can scarcely believe that these comprise all the many subtle points in diagnosis that must have been presented to so able a practitioner. Nor do we think that in the eight cases of which details are given sufficient stress is laid upon the laryngoscopic appearances, although the author is strong in his belief that the laryngoscope is the only means of establishing an early diagnosis. But we consider more might have been said upon this early diagnosis. Thus on page 96 we are told that an ulcer had the characteristic appearance of an advancing epithelioma, although we are nowhere told what this characteristic appearance is. Again (p. 98) an interesting case is related, but as to diagnosis we are informed that "on laryngoscopic examination an epithelioma was observed," of which the apparent extent is mentioned, but nothing of the appearances, while on the following page we are again told of a large ulcerating epithelioma, of which scarcely any particulars are given that would help an inquiring student. No doubt these cases were all easy of diagnosis, but we might have reasonably expected to find in the book some help in the diagnosis of early and difficult

cases We are pleased to see that Dr Newman insists upon the dangers of removing portions of an intra laryngeal growth for purposes of diagnosis unless the patient has previously consented to a radical operation in the event of the microscopical examination proving malignancy. The points in the diagnosis of intrinsic from extrinsic laryngeal growths are admirable and the importance of the distinction is well emphasised. The subjective symptoms are all elaborately given, both in general and in the description of each case, but, as we have already intimated, the points of diagnosis afforded by the laryngoscope, which, if there be anything at all in laryngology, should be all important, are conspicuously insufficient. The remarks on prognosis are excellent. The portions of the work dealing with the surgery of the larynx and operations involving the eradication of malignant disease of the nose are, it need hardly be observed, very satisfactory. Dr Newman's treatment of the subject of malignant stricture of the œsophagus is most instructive, the description of a means of dilatation with tupelo tents being especially interesting. The conclusions as to the value of electrolysis in these cases are very guardedly given, the author telling us that his own experience is not favourable, but that he will not make further experiments until more experience in the use of electricity in other regions has been gained. The book is produced in a manner which reflects credit on the publisher.

LIBRARY TABLE

The Student's Handbook of Surgical Operations By FREDERICK TREVES, F.R.C.S., Surgeon to and Lecturer on Anatomy at the London Hospital, Member of the Board of Examiners of the Royal College of Surgeons, Examiner in Surgery at the University of Cambridge. With 94 Illustrations. London: Cassell and Co. 1892.—This is an abridgement of the author's larger and more comprehensive "Manual of Operative Surgery," and is designed for the use of students who are preparing for their final examination in surgery. The operations are described with commendable brevity, clearness and precision, and only the most essential details are given. The excellence of Mr Treves's "Manual" is generally recognised by surgeons, and the value of this handbook will not fail to be recognised by students.

The Mütter Lectures on Surgical Pathology Delivered before the College of Physicians of Philadelphia 1890-91. By ROSWELL PARK, A.M., M.D., Professor of Surgery, Medical Department, University of Buffalo, Surgeon to the Buffalo General Hospital. St. Louis: J.H. Chambers and Co. 1892.—These lectures were delivered in accordance with the conditions of the will of the late Professor Mütter, under which a series of not less than ten lectures on surgical pathology are delivered at the College of Physicians of Philadelphia. The subjects dealt with are those modern developments which have revolutionised our ideas of surgical pathology and may be described briefly as bacteriological. Dr Park has given in these lectures the results obtained by the many observers at work in the laboratories of two continents and the lectures are a storehouse of valuable information. The rather heavy and unattractive style of the lectures may prevent their being so widely read as their real merit deserves.

Transactions of the Ophthalmological Society of the United Kingdom Vol. XII. Session 1891-92. London: J. and A. Churchill. 1892. Pp. 237.—The papers contained in the volume before us show that those who are following this department of medicine are well abreast of their colleagues in other societies. The Bowman Lecture was delivered by Professor Leber of Heidelberg, who naturally took as his subject the occurrence of inflammation in the eye and the phenomena that accompany it, with which he has been for some years constantly engaged. The paper has wider relations than

with the eye alone and may be read with advantage by physicians and surgeons alike. The volume contains many excellent papers, amongst which we may refer to those of Mr Treacher Collins on the Minute Anatomy of Pyramidal Cataract, of Mr S. Johnson Taylor, on Hereditary Optic Atrophy, of Mr Holmes Spicer, on Retinal Vasculitis in Inherited Syphilis, and of Dr Beevor and Professor Horsley, on Traumatic Abscess in the Brain.

In the *Veterinarian* for this month the Anthrax Order of 1892 by the Board of Agriculture is published. This Order came into force on Jan. 1st and should be carefully studied by all cattle breeders and farmers. At the meeting of the Scottish Metropolitan Veterinary Medical Society held on Nov. 23rd, 1892, a most interesting and important discussion on bronchopneumonia and pleuro pneumonia took place. At present there is a difference of opinion between the Board of Agriculture and the veterinary surgeons of America and Scotland as to the nature of certain cases of lung disease the subjects of which have been condemned by the Board, the Board holding that they are cases of true "pleuro-pneumonia contagiosa," and Principal Williams and his supporters holding that they are cases of simple catarrhal pneumonia. The Scottish Metropolitan Society have suggested, therefore, that the matter should be referred to an independent committee, and, as each party in the controversy seems to be sure of its own position, some such method of procedure seems to be the only way out of the difficulty. It is certainly a very important question, and if the discussion does nothing else it may throw a little light on the pathology of diseases of the lungs in cattle. Proceedings of the various veterinary societies and the examination results of the Royal College of Veterinary Surgeons make up the greater part of the remainder of the number.

* * In the review of *Anæsthetics, their Uses and Administration*—by Dudley Wilmot Buxton, M.D., B.S., Member of the Royal College of Physicians, Administrator of Anæsthetics and Lecturer in University College Hospital. Second Edition. London: H. K. Lewis, 1892.—which was published in our issue of Dec. 17th, 1892, the book was, through a regrettable inadvertence, alluded to, and treated, as a "new manual," whereas it was in fact the second edition of a work published in 1888. We are glad, moreover, to find that our criticism with regard to the apparent omission of any allusion to two recent valuable contributions to the anæsthetist's armamentarium was undeserved, since Dr Dudley Buxton points out to us that they had not been published until after the second edition of his book had passed through the press. It is but fair to the author to add that the present edition of the work has been largely rewritten, is considerably increased in size and has some twenty fresh woodcuts added to its pages. We take the opportunity of correcting a printer's error which occurred in our review by referring to certain specific gravities the expressions "0.656" and "0.720" were used, they should, of course, have been given as 0.656 and 0.720.—ED. L.

METROPOLITAN ASYLUM BOARD—The number of patients remaining in the several fever hospitals of the Board at midnight on Jan. 10th, 1893, was as follows:—Eastern Hospital, 262 scarlet fever, 56 diphtheria and 34 enteric fever, North Eastern Hospital, 405 scarlet fever, North Western Hospital, 300 scarlet fever, 88 diphtheria and 14 enteric fever, Western Hospital, 257 scarlet fever, 34 diphtheria, and 12 enteric fever, South Western Hospital, 258 scarlet fever, 62 diphtheria and 19 enteric fever, South Eastern Hospital, 293 scarlet fever, 16 diphtheria and 1 enteric fever, Northern Hospital, 699 scarlet fever and 9 diphtheria, Gore Farm Hospital, 559 scarlet fever. At the London Hospital and at Guy's Hospital there were three cases, and at Charing Cross Hospital one case, of enteric fever. In the wards of the hospital ship *Atlas* there were 47 cases of small pox on the same date.

New Inventions.

A SIMPLE DEVICE FOR THE UTILISATION OF THE PRESSURE OF A WATER MAIN

MESSRS. C. AND S. FRANK of 10, Fore-street, E.C., have submitted to our notice a very ingenious and simple invention by which the pressure of water in the ordinary main can be utilised for a host of useful purposes. It consists of a hollow globe of metal (made in various sizes) into the neck of which is fitted a tube running within half an inch or so of the bottom. The tube at the top is provided with a tap, while the end of the neck is covered with a rubber washer. A thread is cut upon the outside of the neck for the screwing on and unscrewing of suitable jets. When it is desired to set the apparatus in action, the jet is taken off, and the top of the neck of the globe is pushed tightly against the water tap, the washer between preventing leakage. The water when turned on runs down the tube and partly fills the globe from the bottom upwards. In doing so the air originally contained in the globe is imprisoned and compressed by the rushing water until it attains the pressure of the main supply, when

equilibrium is of course established. The tap of the globe and of the main supply are then turned off and the apparatus detached. A suitable jet is next screwed on. The globe now contains water under a pressure of air equal to that of the main supply. If the tap be turned on, a fine, steady spray of water several feet high (the height depending of course upon the size of the jet) will issue from the jet until almost the last drop has been expelled from the reservoir—until, in fact, the air in the globe has expanded to its original volume. A fine jet will last for hours. It is obvious that by varying the kind of jet the apparatus may be employed usefully for an infinite variety of purposes. For example, it may be used not only as a table or garden fountain, but also for the purpose of a syringe or enema, a throat ear, or nose spray, a food injector, as well as also for the diffusion of scents, medicated vapours, disinfectants and antiseptics into the air of rooms. We have had the invention at work in THE LANCET Laboratory for some weeks, and we find that it not only gives a good jet of water at a convenient force but it acts also for a surprising length of time, while all that need be done when it is exhausted is to apply it once more for a few minutes to the ordinary pressure supply tap. The invention is one likely to afford valuable aid in the practice of surgical and sanitary science.

A NEW THERMOMETER CASE

This useful little contrivance is the invention of Mr Newton Dixon, the Secretary of University College Hospital. The figure shows at a glance the general features of this thermometer which can be attached to a key chain or

watch chain, for which the inventor claims the following advantages: 1. The thermometer is held in its case when the lid is removed by a clamp action which grasps the constriction above the bulb. 2. The temperature can be taken without removing the thermometer from its case, as it can be read through the slot provided for that purpose. (See Fig.)

3. The patient will bite on the case, thus preventing the bulb from being bitten off and swallowed, as sometimes happens. 4. Saving of time—being only one movement in taking off the lid, instead of three or four in the ordinary instrument. 5. Being provided with a ring through which a chain can be passed, the mercury can be easily shaken

down by centrifugal action in the following manner. Holding the end of chain between the finger and thumb, the thermometer case (with lid on to protect bulb of thermometer) being attached to the other end, whirl rapidly round five or six times in a circular direction, when the mercury will be found to be replaced.

INSURANCE AND INEBRIETY

THE second of a series of lectures on inebriety was delivered by Dr Norman Kerr on Tuesday last in the rooms of the Medical Society of London. The subject was "The Relations of Inebriety to Insurance." The lecturer dealt first with assurance against accident. In the usual provision, in accident assurance, of intoxication invalidating a claim, two legal points were involved, one, the establishment of the allegation of drunkenness at the time, the other, that the accident was the true cause of death. On the point whether the assured was drunk, cases were cited showing remarkable conflict of evidence. It was not necessary that the assured should be under the influence of liquor at death. Some offices would not assure publicans, others took them at a considerably enhanced premium. In one case of alleged death by accident the company were successful on the showing that the man was "rotten" with drink and died of alcoholic disease, though a coroner's jury had returned a verdict of accidental death. In life assurances, cases were cited to prove that concealment of intemperance and of delirium tremens was fatal to a claim. In one case on this plea a policy was voided during life. In one case, concealment of a secondary effect of intemperance established resistance, in yet another no report as to habits was fatal. In other cases where there was a mass of evidence indicating intemperance the verdict was against the company. The lecturer dwelt on the interpretation of the word "intemperance," pointing out the opposing views of witnesses and held that there was intemperance which killed but did not make manifestly drunk. Opium re assurance was touched

upon, Dr Kerr stigmatising this drug as destructive of life. As to the commercial relations of assurance, more than a half of inebriate artisans, and at least a third of inebriates of the middle and upper classes were assured. There were two classes of inebriates assured—the inebriate after and the inebriate before assuring. The former generally became drunkards unknowingly and slowly. The loss from both classes was very heavy. Concealment was not always designed. The loss was now borne by policy holders, which was unfair to abstaining lives. To meet this difficulty some offices charged less premium to abstinents. Some diseased inebriates were limited drinkers. There was no standard of intemperance. The initial alcoholic lesion was difficult to detect. As inebriety ages prematurely, a good plan would be to age the policies of drinkers. There should be a loading of "moderate drinking" lives. A new point was the assurance of reclaimed inebriates, whom some offices would not accept. Dr Kerr approved of acceptance after a minimised period of probation of five years in cases of five years standing, with half a year added for every additional year's indulgence. With opium cases the minimum term might be less, with half a year added for every two years' addiction. Chloral and chlorodyne should rank with opium, chloroform and ether with alcohol. Then the lives of the assured ought to be loaded—as regards alcohol with five years (with six months for each additional year of addiction). Policies might, too, be voidable on relapse, with return of the surrender value. The lecturer concluded with a statement of the heavy loss to assurance companies through concealed inebriety and dilated on the importance of the general acceptance of a workable definition of intemperance, the practice of assurance medical examiners presenting striking contrasts

THE LANCET.

LONDON SATURDAY, JANUARY 21, 1893

THE returns of small pox which are made in our columns every week show abundantly that this loathsome malady is continuing to invade fresh districts and at the same time raise the apprehension that we may yet witness a repetition of the extensive outbreak which occurred in Great Britain, as in other countries, two decades ago. Commencing nearly two years ago in a limited but persistent epidemic in the heavy woollen district of Yorkshire, it has not only continued to occur in that county, now extending and now somewhat abating, ever since, but during the latter half of 1892 it visited several towns in the neighbouring counties, and Warrington, Liverpool and latterly Manchester, as well as many other Lancashire towns, have in turn had to cope with exacerbated outbreaks of the disease. Across the border it has invaded Glasgow and Edinburgh, whilst in the north of England Newcastle, Durham and Sunderland have all been visited, and many towns and villages in the Midlands, notably Leicester, are also sufferers, whilst as for the metropolis, it has been visited more than once by the disease since the spring.

The ready manner in which small pox is communicated, the freedom of human intercourse, and especially the facility with which the disease can be introduced by tramps into common lodging houses and poor houses, lend little hope of its arrest until it has covered a far wider area than has at present been invaded. It is an important question which confronts us at this juncture. Is this country better enabled to resist such an invasion now than it was twenty years ago, or does this outbreak find us not much more efficiently prepared to cope with it? In general the answer to this question may be affirmative. There is no doubt that those who have the care of the public health are more fully alive to their responsibilities, and no town of importance is without provision—by notification, isolation, disinfection &c.—for fighting small pox. There is nevertheless a weak spot in England's armour which makes her only too vulnerable to this scourge. Contemporaneous with the period of comparative freedom from the disease there has been increasing agitation against the beneficent vaccination laws, and at the present time they are practically in suspense. In certain districts a large proportion of the children have been denied that protection which their very helplessness should bid us to bestow on them, and when to this is added the comparative laxity with which primary vaccinations are often performed in order to comply with the letter of the law, and the almost entire absence of revaccination except under the pressure of existing local small pox, we find circumstances which undoubtedly contribute to increase the chances of the spread of the disease and the infliction of great suffering.

Theoretically it might appear a simple matter to check an invasion of small pox directly its presence is declared in a locality. The value of the Notification Act in enabling the authorities to be promptly informed of its presence is being

tested in many parts of the kingdom, and we believe that the experience gained therefrom will lead to its general adoption. But even notification cannot meet those cases where the symptoms of invasion are comparatively slight, and where a few days' *malaise*, although sudden in onset and moderately severe in its course, is succeeded by comparative comfort when the scanty eruption appears, and the subject of the illness may never consult a medical man at all. It is just these mild and modified cases that are mainly responsible for the diffusion of the disease, particularly if, as often happens, the victim be a nomadic wayfarer, not very sensitive or observant of his bodily ailments. Then, again, even amongst cases that come under the medical practitioner's observation, there may be some of the characters which are obscure and difficult to interpret. When to such difficulties are added the highly contagious nature of the disease and even—as many facts seem to show—its infectiveness in the pre-eruptive stage, the wonder is not that small pox spreads but that it sometimes ceases to spread as rapidly as it arises.

There can be no doubt at all that promptness in notification followed up by equally prompt intervention of the sanitary authority in removing the patient to a hospital, in disinfecting and cleansing the infected house and in revaccinating all members of the household above the age of twelve as well as all known to have been in contact with the infected person, can do a great deal to prevent the disease spreading from such a centre. Isolation of households, if thoroughly and efficiently carried out, would be a further safeguard, but to rely upon it as a substitute for the protection afforded by revaccination is sure to prove delusive. The system is one which requires a considerable amount of co-operation in those subjected to it, and no amount of inspection or supervision of an infected household can take the place of thorough revaccination. Finally, as regards the diffusion of small pox from hospitals as a centre—so strikingly illustrated at Fulham, Hampstead and Sheffield—the lesson to be learnt is that such hospitals should be situated well beyond the area of inhabited dwellings. For whether, as these instances seem to prove the morbid agents are conveyed aërially in all direction around the centre where the poison is concentrated, or whether they be conveyed directly through the human traffic to and from the institution, the same conclusion may be drawn. Unfortunately in some districts it is not always possible to secure a free and open site for an isolation hospital, and too often the fever hospital is in the immediate neighbourhood of that used for small pox cases. If, as has happened in more than one place lately, there is an unusual demand for the accommodation of fever patients, the introduction of small pox into a hospital, although in a portion of the building set apart for that purpose, may have disastrous results. We have nothing but reprobation for those public bodies who are unprepared with any means of isolation for small pox at the present time. Too many of them pursue a penny wise, pound foolish policy, which finds them unprepared in time of epidemic, to their great cost in money, comfort and life, which a little foresight might have saved them. Happily this spirit of parochial parsimony is giving way to wiser and sounder economy, and in this respect, as in the greater efficiency of our public health

service, we stand on a higher plane to-day than in the days above referred to when small pox was so widely spread throughout the length and breadth of the land.

At the meeting of the Convocation of the University of London on Tuesday last Dr W J COLLINS was placed first, with 855 votes, on the list of the three graduates recommended for the vacancy on the Senate, whilst Mr HOWSE received 642 votes and Mr BENNETT 218 votes. Although Mr HOWSE obtained most of the medical votes, the graduates in the other faculties outnumbered those in medicine and gave Dr COLLINS a large majority. It is therefore quite clear that, although a graduate in medicine or in science is elected alternately with one in arts or laws, yet, owing to the large number of graduates in arts, the latter can always control the election to the Senate, and thus practically select the medical or science graduate to fill any vacancy that may arise on the side of medicine or science as well as on their own. The views of the medical graduates count for but little in the solution of the questions in which they are so deeply interested. Medical difficulties are not understood by the other faculties, and no removal of the grievances of the London medical student is to be expected whilst Convocation retains its present powers, for graduates in medicine and in science will be in a still greater proportional minority in every succeeding year. During the whole of the debate on the scheme of reconstitution, which was passed practically unaltered, only one speaker referred to the medical problem, and he showed how little he was impressed with the importance of the question by saying that the London medical degrees were quite satisfactory, that the Scotch and provincial Universities should no longer be allowed by Parliament to insist on a term of residence, but should be free to all comers, and these Universities should be compelled to raise the standard of their degrees. He completely ignored the whole of the evidence placed before the former Royal Commission, when the Commissioners deliberately reported that the medical degrees of the University were conferred on an honours standard and were not really pass degrees, and that this constituted a grievance of which the London medical student was justified in making complaint. They further suggested that some remedy ought to be found. Notwithstanding this weighty decision and the almost unanimous desire of the medical teachers in London that a pass degree should be available on fair and equitable conditions to medical students who are trained in our metropolitan schools, the other faculties in the University will not hear of any change. It is such action as this which makes a second University a necessity. The tradition of the present University involves merely a high examination standard, but this has served its turn, and what is now required is a local Teaching University in which training as well as examination will have due weight. This is recognised by every teacher in science and in medicine, but is obstinately ignored by graduates in arts and laws, most of whom get their knowledge from a study of books only. Dr COLLINS has been returned as an advocate for the retention of a high examination standard, and as a guardian of the interests of non collegiate students. Such being the view of the main body of the graduates of

the University, it is impossible to expect that Convocation will facilitate any reforms which would either improve the higher education in London or tend to remove the injustice from which the London medical student is at present suffering. The scheme of reconstitution which was passed on Tuesday aims at maintaining or even increasing the powers of Convocation and of adding teaching functions to the sufficiently onerous work which it at present undertakes. The first clause includes, in addition to its existing purposes, "the organisation of regular and liberal education throughout the British Empire, and especially in the metropolis and its neighbourhood, and the advancement of knowledge and encouragement of original research." The Gresham Charter asks only for power to form a local Teaching University, whilst Convocation is ready to organise liberal and regular education throughout the British Empire. An amendment to limit its function to the metropolitan area was lost, but it gave Mr BOMPAS, who led the opposition to the scheme of the Senate in May, 1891, an opportunity of pointing out that the existing University is an excellent Imperial examining board and as such has won a well deserved prestige, whilst what is now wanted for London is a Municipal Teaching University, and he showed that the two things could not be properly combined under one head. This is demonstrated very clearly in the proposals for the formation of a teaching staff. "There shall be a University professoriate and a staff of teachers and demonstrators. All appointments shall be vested in the Senate and shall be held during their pleasure. The Senate shall have power to appoint members of the teaching staffs of the Colleges or other educational institutions as University professors, teachers and demonstrators, with endowments from the funds of the University, on condition that the appointment to such chairs, whenever a vacancy occurs, should pass to the University." Is it really to be expected that the Teaching Colleges, in return for an endowment of a present professor, will submit to having the future occupants of the chair chosen by an outside authority? Again, the University of London has no funds and is dependent on the Treasury for every penny it spends. Lastly, does Convocation contemplate making every professor or teacher in the metropolitan schools a University professor, or does it propose simply to confer this title on only one or more selected individuals? In the case of professorships leading to practice, such as those of medicine, surgery, obstetrics, forensic medicine, and in those of the sister professions of law and engineering, this would be tantamount to saying that these University professors are the greatest experts in the metropolis. The injustice of such a selection needs no comment. It is obvious that no one outside the domain of arts could have brought forward such a scheme, and its unworkable character would render it useless either for negotiation or for compromise. It will hamper the Senate and can scarcely influence the Royal Commission.

THE General Medical Council exercised a wise discretion in leaving to the Registrar General the vindication of the law as respects the false certification of death in the melancholy case of MATILDA CLOVER. The offence is one against the Registration Act of 1874, which enacts (Clause 40 Section 2) that "any person who wilfully

makes any false certificate or declaration under or for the purposes of this Act, or forges or falsifies any such certificate or declaration, or any order under this Act, or, knowing any such certificate, declaration or order to be false or forged, uses the same as true or gives or sends the same as true to any person shall for such offence be liable on summary conviction to a penalty not exceeding ten pounds, and on conviction on indictment to fine or to imprisonment with or without hard labour for a term not exceeding two years or to penal servitude not exceeding seven years."

One explanation, we think, of the laxity that has occurred in filling up such certificates is to be found in the leniency with which the offence has been treated by the Registration authorities. Many cases have been entirely uninvestigated. Prosecutions have been declined and the offenders have come to think that the offence might be committed with impunity. Under the accumulating pressure of juries and the representations of the General Medical Council there has been of late a little more sense of duty exhibited in the Registration Department. The case of MATILDA CLOVER and the consequences of lax certification have roused public attention to the question as it has never been roused before, but even in this case the action of the Registration authorities would seem to have been very slow. At length, however, the matter has been brought into a criminal court and investigated with such care as the gravity of the case demanded. The facts are too recent and too well known to render it necessary to go over them again in detail. Suffice it to say that Mr ROBERT GRAHAM, L.S.A., was sent for, but was unable to attend the unfortunate woman, and that in his absence she was attended by the unqualified assistant of a neighbouring practitioner. The unqualified assistant being unable to give a death certificate, Mr GRAHAM gave one, the said certificate including the statement that he had seen the deceased on the 21st inst. (that is, of October, 1891), and that her death was caused by "delirium tremens and syncope." Mr GRAHAM had not seen the deceased on the 21st until after her death, and the servant of the house in which CLOVER died deposed that she (the servant) told Mr GRAHAM that the woman had had convulsions and that she believed a man had given her some pills. It is to be said, in extenuation of Mr GRAHAM'S offence, that he had quite recently been attending the unfortunate woman for delirium tremens and other complaints incidental to her drinking habits, and that he had nothing to gain by giving the certificate. It was fortunate for him, too, that several medical men were ready and able to speak favourably as to his character. It thus happened that, whilst there was no manner of doubt that he had been betrayed into a great error alike of judgment and of duty, he had erred with no selfish motive and in a way that a jury might consider as due to a mistaken sense of kindness. They accordingly found, after a short deliberation, that he was guilty of having given a false certificate, well knowing at the time that it was untrue, but they added a rider to the effect that he had acted with no bad motive and recommended him to mercy. The Recorder quite agreed both with the verdict and the rider, but he very properly proceeded to point out that the laxity in giving the certificate of death was

most serious and most reprehensible and an offence requiring full investigation in a court of justice, whilst, having regard to the recommendation to mercy and the evidence of good character, he ordered the defendant to be released on his entering into a recognisance in the sum of £100 to come up for judgment if called on, the judge added that in the event of any other similar case coming before him it would be necessary for him to take a very decided course of action.

This is a very clear note of warning and we hope it will be heeded by all medical practitioners. Cases of this kind are happily very rare, but the principle involved is very common, and, though the results of a false certificate are not always so disastrous as in this instance, they are often very serious. In any case, medical men must realise that the signing of a certificate of having attended on a day when they did not attend, or only attended after the death of the patient, is a very serious offence, and one not unlikely in the future to subject the offender to imprisonment. We shall not add to the defendant's pain in this case by emphasising his error. We congratulate him on the recognition of his good character and his well meaning motives. But we think it essential, in the interests alike of the profession and of the public, that this offence should not be ignored, and we are glad that the Recorder has intimated that in the future it will be severely judged by him. We look to the Registration authorities to play their part henceforth with decision and promptitude.

A PROSPECTUS which is being issued by the World's Congress Auxiliary of the World's Columbian Exposition sets forth a general programme of the arrangements which are being made for the holding of meetings during the progress of the Exhibition of persons interested in the discussion of current topics, moral, political and scientific. Thus while, on the one hand, the material exhibits will afford an embodied expression of the present condition of the arts and sciences throughout the world these gatherings will afford an articulate interpretation of the material record and present other aspects of thought which may not be amenable to representation through the medium of physical objects. The function of these Congresses will be, in other and official language, "to review the progress of mankind and state the living problems now awaiting solution." This is a very large commission, and anything less than the machinery of an international exhibition would be manifestly unequal to its execution. But the assemblage of persons from all parts of the world which is destined to take place in Chicago during the summer of the present year will afford unsurpassed facilities for the interchange of observations and opinions. It has been found upon previous occasions that such intercourse may be productive of the most valuable results. It was, for example, at the Congress of Electricians which assembled in Paris during the Electrical Exhibition of 1881 that the international standards of electrical measurement were fixed and the inconvenience of conflicting units in the literature of this science obviated for ever hereafter. Paris was fortunate in this particular. The general progress of events in the electrical world no less than the concourse of well known electricians in the French capital signalled the hour, and it would perhaps be too much to expect of Chicago

that she will be able to make an equally notable contribution to the advance of science in the time to come. But if not it will only be because the hour is not ripe for another equally momentous determination. The organisation sketched in the programme which lies before us is eminently well adapted to utilise the power which will be condensed for a few months upon the shores of Lake Michigan. A very comprehensive scheme of operations has been drawn up, and a procedure devised which should secure in large measure the object with which it has been prepared. That object is chiefly to obtain the results of mature thought in a form adapted for world wide publication. Hence it has been resolved to dispense with open discussion and to impose a strict time limit upon the prepared papers and observations which may be submitted at the various meetings. Through the exercise of a careful choice of representative speakers it is hoped to obtain contributions full of matter for the discussions, and by the time limit it is attempted to secure at once the use of a compressed style on the part of the speakers, which will greatly facilitate the subsequent publication of the proceedings, and a sufficiently large number of contributions to deal adequately with many sided themes.

Among the subjects specified for treatment in which our readers will naturally take a professional interest the first place must of course be assigned to the combined topic of Medicine and Surgery. The meetings in this department are assigned to the week commencing with May 29th, a date which will fall rather early in the year for foreign visitors to the Exhibition. Public Health falls later in the year and will occupy the attention of the Congress in October. It has therefore a better prospect of being successful from the international point of view. In another way also the public health discussions promise to be of greater interest beyond the United States than those in medicine and surgery, and for this reason, that in the sketch programme there is a prominence given to "homœopathic" and "eclectic" medicine which would hardly be assigned to them elsewhere than in America. The public health is a subject eminently amenable to the kind of treatment which these meetings for conference among the unofficial representatives of various nations are well adapted to promote and we hope to be able to record substantial results as the outcome of these deliberations. Some of the subordinate departments of medicine are included in branches of the scheme where they would scarcely be sought, and we think that it would be fortunate if, in the rearrangements which are sure to take place in the preparation of the full and detailed programme, these departments were to be restored to their natural position as branches of the art of medicine. These observations refer particularly to the hospital care of the sick, the training of nurses, dispensary work and the treatment of the insane, which are associated here with the discussion of charities and philanthropy under the aspect of Moral and Social Reform. It is, of course, impossible in the discussion of a vast number of topics of a comprehensive character to avoid all anomalies of classification, nor, indeed, are such anomalies to be feared except in so far as they may tend to withdraw certain topics from the hands of those who may be most capable of dealing with them.

Annotations.

"Ne quid nimirum."

THE LONDON POST-GRADUATE LECTURES

IN connexion with the London Post Graduate Course Sir Joseph Lister delivered a lecture on Wednesday, the 18th inst., in the Theatre of King's College Hospital, on the subject of Antiseptic Dressings. The lecture was eminently practical. A patient was shown who had been operated upon for a badly united fracture of the patella some five weeks before—in operation which, in view of the disastrous effects likely to ensue if septic suppuration occurred, would be unjustifiable unless the surgeon could be quite sure of avoiding septic contamination of the wound. Sir Joseph Lister addressed himself to the means by which constancy of aseptic results in surgical wounds could be attained. The introduction of septic material into a wound during operation in such a form as could develop septic mischief should be prevented and the wound should be treated afterwards in such a manner as to prevent the entrance of septic material subsequently. The two great points which advancing knowledge had revealed were, first, that the blood serum was not a good soil for the development of disseminated and washed microbes, and, secondly, that when these had found an entrance into the tissues, if not in too concentrated a form, they were disposed of by the process of phagocytosis. The practical result of this was that the surgeon might disregard microbes as they existed in air dust, an axiom which greatly simplified surgical procedure. What the surgeon had to contend with was the entrance into wounds of the grosser forms of septic material, such as existed on impure sponges, unclean instruments, dried pus on the teeth of dressing forceps, or the unclean material in the finger nails, or on the skin of the patient. There was a time, in consequence of Professor Koch's publication on the subject, when corrosive sublimate threatened to displace carbolic acid. However, Professor Koch—able as he was—was misled on a certain point and exaggerated the germicidal powers of corrosive sublimate. Sir Joseph Lister attributed the successful results obtained in his surgical cases whilst using corrosive sublimate to the fact that he had always covered the wound with a protective of carbolic acid for the prevention of irritation. In such form as could be used by the surgeon, the sublimate was far inferior to the solution of carbolic acid and water. M. Yersin by experiments made in 1888 ascertained that pure cultures of the tubercle bacilli on glycerine jelly when acted upon by different antiseptics showed that carbolic acid, 1 in 20, killed the bacilli in thirty seconds. At a strength of 1 in 100 they died in one minute, whereas corrosive sublimate, 1 in 1000, required ten minutes for their complete destruction. Further, Professor Crookshank had at his request injected at King's College laboratory certain guinea pigs with pure cultures of the most resisting form of tubercle bacilli—that prepared from human sputum. He also injected other guinea pigs with similar cultures, which had been treated before injection with solutions of carbolic acid and water of different strengths. The injections were made into the skin of the thigh, and the results, when the animals were examined on Tuesday last, demonstrated that whilst the untreated tubercle bacilli readily gave rise to tubercularisation the samples which had been treated by carbolic acid solutions of a strength greater than 1 to 100 effectually prevented this. Regarding dressings he said that in the absence of antiseptics dry rags kept the soil less favourable for the development of microbes than water dressings. Iodoform had been very much praised by some surgeons, and

it was a very peculiar antiseptic, exerting comparatively little antiseptic power outside the body. It had been ascertained that a growth of organisms could be obtained from iodoform itself. It, however, undoubtedly possessed a remarkable antiseptic effect in the tissues. On the field of battle it was a question whether this was not the best agent at the disposal of the surgeon, but other means, if possible, should be preferred. The best arrangement was the employment of a chemical antiseptic which would securely prevent septic material getting into the wound. Three conditions were necessary in such an agent—it must be antiseptic, it should be in such a form that it would adhere to the dressing and not be washed away between one dressing and another, and it was very desirable that the material should not be irritating. Sir Joseph Lister pointed out that on the whole a combination of gauze steeped in a solution of carbolic acid of 1 to 20 and subsequently dusted over uniformly with cyanide of mercury and zinc fulfilled these three conditions most efficiently. He demonstrated the mode in which the surgeon could himself prepare this dressing at a cost not exceeding 4d per dressing. We propose to publish Sir Joseph Lister's very interesting lecture *in extenso* in an early number.

THE PREVALENCE OF SMALL-POX

THE number of localities from which news comes of small pox is steadily increasing, but as yet the disease has not exhibited any tendency to diffuse itself rapidly and on a large scale except in a few places. Perhaps one of the main difficulties that has for the moment to be faced is the movement of tramps to and from infected places and workhouses. In a number of workhouses the disease has already broken out, and this in turn gives prominence to an old dispute as to who is to look after a small pox patient when he is a pauper. Clearly the sections of the Public Health Act, 1875, which deal with the prevention of infection never intended that sanitary authorities should isolate the infected non pauper and that the poor law guardians should not be required to deal in the same way with the infected pauper. Isolation is a function carried out in the interests of the public health as a whole and not of the health of a particular portion of the community. But, notwithstanding this, certain difficulties arise owing to rules affecting the administration of the poor law. The guardians are bound to see that paupers and destitute persons are provided with proper accommodation, nursing, food and treatment when ill from any disease, and hence probably the suggestion contained in Section 132 of the Act which implies that in the case of a pauper any debt for his maintenance is recoverable not from the pauper himself but from the guardians. But have guardians any such function in dealing with infectious cases as carries with it requirements involving the protection of the public health? Again and again has this subject been discussed, but, whilst it has never been definitely decided that the poor law authority has any such function, it is perfectly clear that the duty of providing isolation hospitals for the use of "the inhabitants" is a duty cast upon sanitary authorities. At several places in the north, and notably at Rotherham, this question is now pressing in an acute form, and it is likely to arise elsewhere, because, whilst guardians still have their duties to perform towards the sick pauper, the rural sanitary authorities have rarely availed themselves of the permissive power of erecting infectious hospitals, by which alone they can secure isolation. Another feature of the prevalence is the rush after temporary hospitals, which in our climate are unfit for permanent use, which have often acted as a mere block in the way of the provision of proper hospitals, and which are often deemed to be a first necessity when so preventable a disease as small pox occurs, whereas no means of isolation are thought of when the other specific fevers, which

cause an infinitely greater mortality than small pox does, are continuously occurring in our midst. Unfortunately too, the usual difficulties as to diffusion of small pox from hospitals are also transpiring, the most notable instances during this epidemic being the diffusion which has resulted either to the population generally or to patients in other ward blocks, or to both, at Warrington, Leicester and Oldham. In the meantime, as we have pointed out, the disease is extending and the country is unprepared to meet the emergency both as regards proper hospitals and efficient general re vaccination. Amongst the places from which news of small pox comes are the following: Acton Grange, on the Manchester Ship Canal, Bentham, Brimington, Bromsgrove, where the disease appeared in a common lodging house, Castleford, where importation from Leeds is suggested, Chadderton, near Oldham, where 20 fresh attacks were recorded last week, Cleckheaton, Chestrele-Street, Chapel en le Frith Workhouse, Densby Main, Dewsbury, Frodsham Marsh, on the Manchester Ship Canal, Gateshead and Houghton le Spring, where cases are arising in the workhouses, Halifax, where 13 new cases have occurred, some in the workhouse, Hartlepool, where common lodging house tramps are affected, Hexham workhouse, Huddersfield, model common lodging house, Keighley, Lancaster, Leeds, where 53 cases were under isolation last week, Leicester, where a sudden exacerbation has taken place, 21 fresh cases being reported last week, with further attacks this week, Louthwaite, Macclesfield, Manchester, where the disease is extending and a new hospital is to be erected, Mexborough, Middlesbrough, Northallerton rural district, Nottingham, Ossett, Oldham, where 12 fresh attacks occurred last week, Pontefract, Rotherham, where owing to the workhouse being infected Dr Downes of the Local Government Board is advising the guardians, Runcorn, Southampton, where 13 new cases have just occurred, Stamford, Stockton, Sunderland, where the disease appeared in the casual wards of the workhouse and in a common lodging house, and where 5 new attacks occurred last week, Todmorden, West Halton, and Winterton, in North Lincolnshire. Between 50 and 60 cases are under treatment in the hospitals belonging to the Metropolitan Asylums Board. Small pox is also spreading in various parts of Scotland and notably in Glasgow where 34 new cases have occurred within ten days. The story is a serious one at this especial season of the year. No newly improvised hospitals can be expected to stay the spread of the disease, there is only one real remedy—namely, vaccination and revaccination of all who are upwards of twelve years old, and resort to this protective should be urged by all medical practitioners and public officials.

RESISTANCE TO COLD

THE death of a centenarian Italian in a Norfolk town the other day, whose chequered life-history included service in Napoleon's "Grande Armée" during the disastrous Russian campaign of 1812, recalls attention to the fact that, of all that host, the Neapolitan contingent, 10,000 strong, withstood the cold and privations much better than the other divisions, recruited as these mainly were from North western and Central Europe. So interesting and unexpected was this phenomenon, put on record by Baron Larrey, head of Napoleon's army medical staff, that the physiologists and hygienists of the time hazarded many explanations of it—explanations revived and checked during the Crimean campaign forty years ago, when again the Italian regiments of the allied forces were found to suffer less from the Russian winter than their French or even British comrades. The view taken of the fact was this: that the Italians, born and reared in the sunny South, retained so much "caloric" in their systems that their supply of it continued long after their fellow soldiers from less favoured climes had used up

theirs In support of this the experience of other Italians was invoked who, as teachers or artists had settled in English or Scottish educational centres and whose power of weathering the first northern winter was much greater than during the second and third, by which time, it was contended, their supply of "caloric" was exhausted and they were fain to have recourse to the creature comforts for which at first they had a positive repugnance. Australian colonists and Anglo-Indian officers, on their return to the mother country cited their experience in a similar sense, and Claude Bernard's "*Chaleur Animale*" (1876) came afterwards to translate those popular induction into scientific language. No doubt during those Russian campaigns the Italian troops, new to such a climate and to such winters, felt the keenly oxygenated air as a stimulating, restorative influence rather than as a depressing one, and all through the several weeks of their subjection to the novel conditions the "systemic response" to these declared itself in a heat production considerably in excess of the heat loss. The question of course arises—could that "systemic response" continue at its maximum of force the second winter? Experience answered in the negative, and the testimony of Italian civilians resident in the British Isles, as well as of the Australians and Anglo-Indians aforesaid, points to the same conclusion. One element in the explanation of the phenomenon, however, must not be overlooked, and that is the greater temperance of the southern as compared with the northern European. To the former—and this was especially marked in the disastrous retreat from Moscow—the abuse, or even the sparing use, of alcohol was all but unknown. This abstinence put the Italian at a mighty advantage over the northern soldier, who, as Sir Walter Scott has placed on vivid record, flew to cognac or vodka whenever they could get at it, and considered themselves happy if they could purchase 'some hours of insensibility by intoxicating liquors. Then again, Italians in general and Neapolitans in particular, inured to the scantiest meals of macaroni and salad, felt the starvation diet of the forced marches much less than their French or Teutonic comrades. The same must also be said in the matter of clothing—the Neapolitans, even in abnormally cold winters, contenting themselves with an artificial warmth in raiment and fuel much below that to which the northern races are accustomed.

PROFESSIONAL EXCLUSIVENESS IN SWITZERLAND

By her own confession Switzerland relies on the foreign visitor for a very large proportion of her revenue. In seasons when this "import" is "conspicuous by its absence" the disappointment and dismay throughout the cantons soon find a voice. Apart from hotel keeping—that is from providing for the import in question—there are not many lucrative enterprises in Switzerland—a fact which was illustrated some fifteen years ago when she had an exposition of native industries. So poor was that affair that her apologists were fain to account for it by the fact that nearly all the young energy and talent of the people go into hotel keeping and that all other interests particularly the manufacturing and artistically productive ones were proportionately impoverished. Such being the case, it is surely ill advised as well as ungracious on her part to adopt the exclusive policy she enforces against one adjunct of the "foreign" visitor—to wit, the medical practitioner—who accompanies him. The columns of THE LANCET have frequently borne testimony to the severity of cantonal law as exercised on the British physician or surgeon who ventures on professional work in the chief places of tourist resort, and now we have a similar complaint brought from another nationality against the same exclusive spirit. Italian Switzerland, represented by the Canton Ticino with its headquarters at Bellinzona, has just met in Grand Council and has carried a law

forbidding the practice of medicine, pharmacy, dentistry or the veterinary art to all unprovided with the federal diploma. This enactment bears heavily on the practitioner from the Italian schools whose professional qualifications have hitherto been recognised—and justly—in the Canton Ticino as equal to those of the federal examining boards. Physicians and surgeons who have found much acceptance with their respective *clientele* must if they have the misfortune to have graduated in a non Swiss, though possibly superior, school, be henceforth precluded from practice unless they submit to the inconvenience and expense of passing a Swiss examination. Surely registration as a duly qualified British, French or Italian practitioner should satisfy the Confederation of its possessor's right to visit patients of his own nationality without the exaction of a federal diploma. Should this exclusive policy be persisted in, Switzerland must not be surprised if the stream of tourist travel flows away from her borders and seeks new holiday or health resorts in adjacent countries where more liberal laws prevail.

THE RIGHT OF THE PUBLIC TO DEMAND INSTANT ATTENTION FROM MEDICAL MEN

At an inquest touching the sudden death from aneurysm of Elizabeth McCarthy, aged fifty seven, at the coroner's court, High-street, Borough, an indignant juryman waxed very warm over the absent parish doctor because he did not respond to the message sent. On the coroner saying that a parish doctor might require an order before attending a case, the juryman considered "it disgraceful" and thought "we ought straightway to stop our rates." He pointed out very properly that if in a case of ruptured varicose vein a medical man promptly obeyed the call life might be saved and *vice versa*. The medical officer at whose expense this cheap moralisation was delivered was not present to state his case. We would only say that practically the medical man does respond promptly, as no other man does to the cry of pain and peril—"his ready help is always nigh." And very little does the public care to see the other side of the account stated and its own duty enforced. We would urge the juryman in this case to use his energy in the study of other parts of this great question and to procure for the public, by proper and just arrangements the right to summon the first available medical practitioner in cases of emergency.

THE VACANT CORONERSHIP FOR CORNWALL, WESTERN DIVISION

THE local county council will shortly have to elect a coroner for this district. For the vacancy there are five candidates, three of them being solicitors and two members of the medical profession. The two latter are Mr Richard Charles Mason Pooley L.R.C.P., L.R.C.S.I., of Falmouth, and Mr Arthur Edward Permewan, M.D. M.R.C.S. Eng. Dr Permewan also possesses a qualification in State Medicine from the London University and is likewise a diplomate in Public Health of Cambridge. Leaving the county council to decide between these two gentlemen, we proceed to reiterate the reasons why they should elect a medical in preference to a legal candidate. There never was a time when death certification was more on its trial than it is now and the most responsible duties which coroners have now to perform are those of deciding whether an inquest is or is not necessary, whether medical evidence is to be received and whether a post-mortem examination should be made. Should an inquest be considered unnecessary the coroner is required to inform the registrar of the sub-district of this and also as to what is the supposed cause of death. Let us assume that a solicitor without any previous medical training is elected to perform these duties, it is manifest that he is as perfectly ignorant of them all as a medical

practitioner would be of the duties of a town clerk. The viewing of the body, the preliminary inquiries, the weighing of statements as to symptoms during life and of appearances after death, are all matters in which solicitors have no previous training and with which they are perfectly incompetent to deal. For some time after their election legal coroners have to learn their duties with such coaching as they can obtain from the beadle or coroner's officer, who in his turn is quite incompetent to perform any but the most subordinate duties. Moreover, when inquests are held they show their want of medical training, hence it is that so many useless inquests take place and so many ridiculous verdicts are returned. The medical coroner who has studied State Medicine and who has had some experience as a witness in coroners' courts commences his duties under very different auspices. The viewing of the body is a duty to which he comes as an expert, having been trained to it from the day when he first became a medical student. Years of study have made him thoroughly acquainted with disease and death in all their forms, whilst as to the taking of evidence the treatment of disease and injuries is "a taking of evidence" of the most searching kind. We hope that the county councillors who have to make the appointment will keep strictly before their minds what is the object of every inquest which the new coroner will have to hold. It is to ascertain the cause of death, how when, and where it was caused. This can only be done with entire satisfaction by a coroner who has had a complete medical training, and who has been prepared for the legal part of his duties either by the study of State Medicine or by considerable experience as a witness in the coroner's court and as an expert in the making of post-mortem examinations.

STUDENTS IN THE SCOTTISH UNIVERSITIES

THE *Edinburgh Evening Dispatch* of Jan. 12th, 1893, gives the following interesting statement of the numbers of matriculated students in Edinburgh University for the past four years—

Year	Arts.	Divinity	Law	Medicine	Total
1880 --	981	124	472	2025	3602
1890 --	940	110	408	1679	3536
1891 --	942	88	495	1830	3354
1892	881	82	490	1715	3138

Total diminution during the four years, 464—made up of 100 arts, 42 divinity, 12 law, 310 medicine. The corresponding figures of Glasgow University are as follows—

Year	Arts.	Divinity	Law	Medicine	Total
1880	990	95	192	818	2101
1890 --	996	88	197	770	2053
1891	972	93	206	820	2091
1892	941	83	205	700	1929

Net diminution during the four years, 106—made up of 55 Art, 6 Divinity, 58 Medicine—less increase in Law, 13. The foregoing figures do not, in the case of either University, include students enrolled in non curriculum classes on payment of 5s fee, or include female students. For the current session 127 women are matriculated at Glasgow and 70 at Edinburgh.

BRITISH MEDICAL BENEVOLENT FUND

THE annual general meeting of subscribers to the British Medical Benevolent Fund was held on Jan. 12th at 84, Brook street, Grosvenor square, the residence of the treasurer, at 4 P.M., Sir James Paget, Bart., F.R.S., President, in the chair. The report which was read showed that during the year 1892 the receipts were £5927 13s. 9d., the subscriptions and donations amounted to £2709, the income from invested property to £2064, and the legacies to £1153. The sum of £2200 had been invested during the year, including £1150 subscribed by the friends of the late Mr. J. Morgan, F.R.C.S., to form an annuity in connexion with his name. The grants voted to

urgent cases, numbering 140, varied from £5 to £20 and amounted to £1657, and the sum of £2030 was bestowed on annuitants of over sixty years of age. The whole organisation of the fund was carried on, as before, by voluntary workers both in the collection and distribution of the funds. The report was received and votes of thanks were passed to the President, to Dr. Broadbent (treasurer), to Dr. Sidney Phillips and Mr. Edward East (hon. secretaries) and to the auditors, the medical press, and others connected with the working of the charity. Drs. Prickett, Bowles, and F. Taylor and Mr. Parker Young were elected members of the committee, and the following Vice Presidents were also elected: Drs. Holman, Felce, Birkbeck Nevins and Messrs. de Styrap and Terry.

DEATHS UNDER ANÆSTHETICS

Two deaths have been recently reported as occurring when ether had been administered, but in both instances the fatalities appear to have been rather due to the state of exhaustion in which the patient was at the time of the administration than a direct result of the ether. In the one case, which occurred a week or so back at the London Hospital, the patient, a billiard marker, had suffered for some years from an internal complaint. His medical attendant directed his removal to the London Hospital. He was admitted in a very feeble state and in great agony, and, an operation being imperative, Mr. Treves directed that an anæsthetic should be given. Ether was selected as giving the man the best chance in the critical condition in which he was. The patient went on well for eight minutes, when respiration ceased and the heart failed. Restorative measures were fruitless. The next case occurred at Abingdon. A woman aged forty-seven was admitted into the Cottage Hospital suffering from strangulated hernia. The patient, having been duly anæsthetised, was operated on and the operation was successfully completed. It is stated in the report before us that the patient never entirely recovered from the effects of the ether and died two hours later. We are, unfortunately, not told what the particular effects of the ether were or how the ether was given or what was the quantity employed. It is certainly a very unusual thing for a patient to remain under the effects of ether for two hours after the completion of an operation such as that for the relief of strangulated hernia, which, as a rule, does not occupy much time and therefore does not require the use of more than an ounce or two of ether. It would seem more consonant with our experience of such cases that the severe shock attending the condition played the principal part in bringing about the unhappy results.

THE FRIENDLY SOCIETY MEDICAL INSTITUTE AT LUTON

THERE has been great rejoicing at Luton over the opening of what is called the Friendly Society Medical Institute, the cost of which, exclusive of ground, is to be £2500. The whole cost is likely to be about £3500. Such a building will doubtless be very convenient. The occasion was graced by the presence and the speeches of Lord Batterssea, the Mayor of Luton, Mr. S. Howard Whitbread M.P., Colonel Cook and other distinguished gentlemen. The speakers all felt a liberty to speak in terms of unqualified approval of the Institute and its objects. They could scarcely be ignorant of the fact that the methods by which these institutes are promoted and the objects aimed at by their promoters are the subject of very serious question and doubt, and are indeed a present matter of inquiry by a committee of the General Medical Council. We may be sure that such gentlemen as we have named would not support them if they did not believe what one of the speakers said, that "the benevolent and philanthropic principles of these societies were unquestionable." If other critic-

are to be believed they impose on the unfortunate medical officer an amount of work which is altogether monstrous for one man. We suspend our own judgment on these matters out of respect alike to the General Medical Council and to the Associations concerned. So strongly have we felt it our duty to do that we have ceased to publish correspondence or comment on the subject, trusting that all parties concerned will help to make the investigation of the Council complete and its conclusions reasonable. In noticing the report in the *Luton News* of the opening of the new building and the rostrate and laudatory views of the speakers we would only remind them through our readers that there is another side to the question, which was almost entirely overlooked by the orators on the opening day, but of which we shall doubtless hear in due time.

INTERNATIONAL MONUMENT TO SEMMELWEIS

At a meeting of the North London Medico-Chirurgical Society, held on the 12th inst., Dr J. G. Glover brought before the members the claims of Semmelweis and appealed to them to assist in establishing an international memorial to the man who, fifty years ago, demonstrated the necessity for antiseptic precautions in all midwifery practice. We understand that the Obstetrical Society has also made an appeal to its Fellows to combine with all those who recognise the value of Semmelweis's work in contributing to this scheme. We trust that the Executive Committee, of which Sir Spencer Wells is chairman, may be encouraged by a liberal response from the members of the profession in this country and may thus be enabled to send to Budapest a contribution worthy of British medicine. Dr Cullingworth (honorary treasurer), 46, Brook street, W., will acknowledge any contributions.

"PLETHORA UNIVERSITARIA"

If this malady has not yet found classification in the pathology of public instruction it must be because of its limited, not to say unique, incidence. In fact, it is in Italy only that it is seen to exist. For a population of under 30,000,000 she has twenty-one universities. This is explained by the circumstances under which she became a united Kingdom. Each successive duchy, archduchy, pontificate or sovereignty that ceased to be "a geographical expression" and was absorbed into Italy, "one and indivisible," had its university or universities—some of these ancient and renowned, others scarcely even heard of. The present Minister of Public Instruction (Signor Martini) wants to suppress the languishing ones, and by concentrating the State largess on the really vigorous survivors to advance the cause of academic reform. A tempest of indignation has arisen in consequence, and meetings protesting against his "illiberal measure" are being held all through the peninsula. His answer is that by topping off the withered and decaying branches of the academic tree he is safeguarding the health and efficiency of the parent trunk. And what are the facts? We take them from Signor F. Dobelli, an Italian publicist, whom no one will suspect of reactionary sympathies. Piedmont, with 3,000,000 inhabitants has one university. Turin, Liguria, with 1,000,000, also one, Genoa. Lombardy with 4,000,000 one, Pavia, the Venetian territory with 3,000,000 one, Padua, the Neapolitan, with 8,000,000 one, Naples, Latium, with 1,000,000 one, Rome. Now for the other side. The Emilia, with 2,500,000 souls has four universities—Parma, Modena, Bologna and Ferrara, the Marches and Umbria, with less than 2,000,000 also four—Camerino, Macerata, Urbino and Perugia. Sicily with 3,000,000, has three—Palermo, Catania and Messina, Tuscany with 2,000,000 has two—Siena and Pisa, the island of Sardinia, with something over 600,000, has two—Sassari and Cagliari. It is asked, if six universities suffice for a population of

20,000,000 why should the other 10,000,000 Italians complain if eight or ten of their fifteen universities are suppressed? Again, the six greater universities admit 8000 students, the other fifteen enrol less than 3000, while there are universities, according to Signor Dobelli, where there are fewer students than professors! In the interests of Italian progress Signor Martini justifies his measure of suppression. Italy suffers from a traditional provincialism. What better cure for this than, by reducing the number of universities to compel students from a wider area to meet in one or other of the greater ones and by contact and friction rub off their parochial angusties? The small universities on the present system, are so poor that they cannot keep pace with science in the requisite appointments such as tutorial staff, laboratories, libraries &c. This evil would be met by the simpler means at the disposal of the better attended, better endowed, and larger ones. To retain the full number of Italian universities, but to cut down their faculties—restricting one, for instance, to law, another to medicine, a third to exact science, and so on, and limiting their power of granting degrees to the one faculty they represent—is a proposal which has only to be stated to be dismissed. Signor Dobelli asks where the lawyer is to acquire his medical jurisprudence in a university which ignores medicine and teaches only law, or where the medical graduate is to get his exact science in a school where physics, optics, &c. are not recognised. Universities would forfeit their name under such a system. Meanwhile the issue of the battle in which Signor Martini courageously encounters the champions of the *status quo ante* will be watched with interest.

SMALL-POX IN SCOTLAND

At Glasgow Dr Russell reported on Monday that 18 cases of small pox were intimated for the fortnight, as compared with 9 in the preceding fortnight. Of these, 2 occurred in the first week, and 16 in the last four days of the second week. They were distributed thus: Central District, 4; Southern, 3; Northern, 1; Eastern, 10. The following notes are reproduced from his report—1. On Jan. 4th, Mrs. X—and her unvaccinated infant aged two months were reported in the Eastern district. The baby has since died. On the same day the case of Mrs. Y—who keeps a milk and grocery shop in the adjoining tenement, living in the back premises was also reported. Inquiry led to the discovery of the following facts. On Dec. 12th a factory girl who lodged with Mrs. Y—fell ill and during the ensuing fortnight was away from work. She occupied a bed in a room behind the shop. She was engaged to a brother of Mr. X—, and was in fact married on Dec. 30th. Mrs. X—with her baby, visited the girl in the middle of the week before Christmas. Following this clue the newly-married woman was visited at her house on Jan. 5th, and, most distinct evidence of a recent attack of small pox being still recognisable she was transferred to the hospital. In the tenements within the period embraced in this report two cases have occurred, but it is impossible to anticipate, and can never be directly traced, how much mischief has been caused by this dispensation of small pox with milk and groceries and this marriage of a person suffering from small pox. Several of the cases in the Eastern district are amongst factory workers. 2. Five cases belong to the model lodging house class whose nomadic habits make them a special source of danger. One man who lives in Partick and was in frequent intercourse with this class walked into the sanitary office with a copious eruption on his face, saying that a friend who met him in the street told him he looked as if he had the small pox and advised him to call at 1, Montrose-street. A girl in charge of a doctor's shop into which one of these nomads went, who was found to have small pox, was the only one of ten persons in the shop at the time who

practitioner would be of the duties of a town clerk. The viewing of the body, the preliminary inquiries, the weighing of statements as to symptoms during life and of appearances after death, are all matters in which solicitors have no previous training and with which they are perfectly incompetent to deal. For some time after their election legal coroners have to learn their duties with such coaching as they can obtain from the beadle or coroner's officer, who in his turn is quite incompetent to perform any but the most subordinate duties. Moreover, when inquests are held they show their want of medical training, hence it is that so many useless inquests take place and so many ridiculous verdicts are returned. The medical coroner who has studied State Medicine and who has had some experience as a witness in coroners' courts commences his duties under very different auspices. The viewing of the body is a duty to which he comes as an expert, having been trained to it from the day when he first became a medical student. Years of study have made him thoroughly acquainted with disease and death in all their forms, whilst as to the taking of evidence the treatment of disease and injuries is "a taking of evidence" of the most searching kind. We hope that the county councillors who have to make the appointment will keep strictly before their minds what is the object of every inquest which the new coroner will have to hold. It is to ascertain the cause of death, how, when, and where it was caused. This can only be done with entire satisfaction by a coroner who has had a complete medical training, and who has been prepared for the legal part of his duties either by the study of State Medicine or by considerable experience as a witness in the coroner's court and as an expert in the making of post-mortem examinations.

STUDENTS IN THE SCOTTISH UNIVERSITIES

THE *Edinburgh Evening Dispatch* of Jan 12th, 1893, gives the following interesting statement of the numbers of matriculated students in Edinburgh University for the past four years—

Year	Arts.	Divinity	Law	Medicine.	Total.
1880 ---	981	184	472	2025	3662
1890 -	940	110	408	1979	3637
1891 --	942	88	435	1830	3355
1892	881	82	460	1716	3139

Total diminution during the four years, 464—made up of 100 Arts, 42 Divinity, 12 Law, 310 Medicine. The corresponding figures of Glasgow University are as follows—

Year	Arts.	Divinity	Law	Medicine	Total.
1880	990	95	102	818	2105
1890 ---	998	88	107	770	2063
1891	972	93	200	820	2091
1892	941	89	205	700	1935

Net diminution during the four years, 106—made up of 55 Arts, 6 Divinity, 58 Medicine—less increase in Law, 13. The foregoing figures do not, in the case of either University, include students enrolled in non curriculum classes on payment of 5s fee, or include female students. For the current session 127 women are matriculated at Glasgow and 70 at Edinburgh.

BRITISH MEDICAL BENEVOLENT FUND

THE annual general meeting of subscribers to the British Medical Benevolent Fund was held on Jan 12th at 84, Brook street, Grosvenor square, the residence of the treasurer, at 4 P.M., Sir James Paget, Bart., F.R.S., President, in the chair. The report which was read showed that during the year 1892 the receipts were £5927 13s 9d, the subscriptions and donations amounted to £2709, the income from invested property to £2064, and the legacies to £1153. Meanwhile the issue of the battle in which Signor Martini courageously encounters the champions of the *status quo antea* will be watched with interest.

SMALL-POX IN SCOTLAND

At Glasgow Dr Russell reported on Monday that 18 cases of small pox were intimated for the fortnight, as compared with 9 in the preceding fortnight. Of these, 2 occurred in the first week, and 16 in the last four days of the second week. They were distributed thus: Central District, 4, Southern 3, Northern, 1, Eastern, 10. The following notes are reproduced from his report—1. On Jan 4th Mrs X—and her unvaccinated infant aged two months were reported in the Eastern district. The baby has since died. On the same day the case of Mrs Y—who keeps a milk and grocery shop in the adjoining tenement, living in the back premises, was also reported. Inquiry led to the discovery of the following facts. On Dec 12th a factory girl who lodged with Mrs Y—fell ill and during the ensuing fortnight was away from work. She occupied a bed in a room behind the shop. She was engaged to a brother of Mr X—and was in fact married on Dec 30th. Mrs. X—, with her baby, visited the girl in the middle of the week before Christmas. Following this clue the newly-married woman was visited at her house on Jan 5th, and, most distinct evidence of a recent attack of small pox being still recognisable she was transferred to the hospital. In the tenements, within the period embraced in this report, two cases have occurred but it is impossible to anticipate, and can never be directly traced, how much mischief has been caused by this dispensation of small pox with milk and groceries, and this marriage of a person suffering from small-pox. Several of the cases in the Eastern district are amongst factory workers. 2. Five cases belong to the model lodging house class whose nomadic habits make them a special source of danger. One man who lives in Partick and was in frequent intercourse with this class walked into the sanitary office with a copious eruption on his face, saying that a friend who met him in the street told him he looked as if he had the small pox and advised him to call at 1, Montrose-street. A girl in charge of a doctor's shop into which one of these nomads went, who was found to have small pox, was the only one of ten persons in the shop at the time who

refused revaccination and is the only one infected. Another man who shifted from one "model" to another turned up at the office with small pox, and it was ascertained that on the previous day a charitable clergyman had taken him into his house and given him dinner and some clothing. 3. A man who sickened in Manchester on Dec 21st came on to Glasgow on the 23rd and next day went to the Saturday afternoon concert in the City Hall. He was not able to sit out the entertainment and was removed to Belvidere on the 26th. He had the eruption since the 23rd and used fully all the public means of locomotion in the interval. The total number of cases existing in Glasgow on Monday was 42, an increase on previous figures. Barlinnie Prison, near Glasgow, appears to have been a centre of small pox distribution. Two cases in Glasgow, one in Slamannan (Stirlingshire) and another in Wishaw (Lanarkshire) had their origin in this prison. Every effort is being made to prevent further spread from this institution and to trace existing cases. No new cases are reported from Dumbartonshire. The navy who set a going the infection near Helensburgh went on to Crianlarich in Perthshire and has been got hold of there, so that his career as a propagator of small pox has been brought to a termination. In the Edinburgh district we have not heard of any fresh outbreak. The Board of Supervision has issued a circular impressing on local authorities the urgent need for attention to vaccination, to removal of nuisances and to the provision of hospital accommodation.

SINGULAR CASES OF POISONING BY GAS FROM A DISUSED MINE

EMANATIONS of carbonic acid gas from the earth, except from springs or in the neighbourhood of volcanic districts, are comparatively rare, and the occurrence reported in the papers on Tuesday must be considered somewhat unusual. It appears that in a mining village close to Wolverhampton two women died last week from the effects of a gas which is believed to have exuded from the neighbouring disused coal mines into the cellars of the houses which they inhabited. The women who succumbed were found lying on the floor in convulsions, and some domestic animals also succumbed in the same house. The coroner's jury returned a verdict in the case of each of the two women of "Death from congestion of the lungs caused by inhalation of carbonic acid gas." It is difficult to account for this gas issuing from a disused coal mine. Coal has the remarkable property of storing or occluding inflammable gas (CH_4) within its substance, but this property does not extend to carbonic acid. Carbonic acid is of course familiar to the miner as the deadly afterdamp or chokedamp which follows an explosion, but in a disused mine the production of carbonic acid from this cause is out of the question. Whatever the origin of the gas may have been there can be but one conclusion as to the necessity of avoiding further disaster. The cellar floors of houses contiguous to coal mines should be lined with a cement which is impervious to gases, and the passages of mines that have been exhausted of their coal should never be allowed to get choked with waste material or rubbish.

NEGLECT TO PROVIDE ISOLATION FOR INFECTIOUS DISEASES

WE have frequently called the attention of the profession to the neglect of sanitary authorities in providing the necessary hospitals for the isolation of infectious cases occurring in their districts. The penalty of such neglect must sooner or later be felt. A case of small pox occurred recently in Standish, a village near Wigan, which may yet lead to awkward consequences through such neglect. A man who had come originally from near Manchester and had

passed several days in the vicinity went into the surgery of the local practitioner and medical officer of health, who recognised the symptoms as those of small pox. The Standish local authorities, although their district is seldom free from infectious diseases such as typhoid fever and scarlet fever, have neglected to provide an isolation hospital. No empty house could be obtained, and no one could be found to admit such a case into his house. After several hours' delay the relieving officer of the district had the man taken to the Wigan Union Workhouse. The master, on learning the nature of the case, refused the patient admission because there were no infectious wards attached to the workhouse, and eventually the man was admitted into the Wigan Sanatorium. The Wigan Board of Guardians have had an arrangement for some time with the Sanitary Committee of the corporation by which all infectious cases occurring on their premises or in their schools are at once removed to the corporation isolation hospital. By this means several outbreaks of small pox have been averted. Although for relief purposes Standish is within the Wigan Union, the local sanitary authorities are expected to make provision in their own districts. Several local boards have done so, whilst other districts of the union have neglected this most important duty. It is to be hoped that this case will arouse the authorities from their state of lethargy. They should either provide a suitable hospital at once or combine with neighbouring authorities for the purpose. In his last report to the Standish Local Board, Mr Marsden, the medical officer of health, reported (in writing of scarlet fever) that "disinfection and isolation were effected so far as circumstances would allow, but until we have an infectious disease hospital this class of disease will always find here a happy hunting ground."

THE DEATH OF MR SUMMERS, M.P.

A correspondent of the *Huddersfield Chronicle*, "Sanitas," referring to the lamentable death from virulent small pox in India of Mr Summers, says "he was a strong opponent of vaccination and had the courage of his opinions. It is sad to think that had he been revaccinated before he left his native shore he might have escaped so tragic a death." We have only two alterations to make in the last sentence. We should insert the word *successfully* before vaccination and substitute the word "would" for the word "might." These alterations, though not to be taken absolutely, are amply justified by experience. It is lamentable to think that with the rising flood of small pox in our own country there is a huge number of unvaccinated and unrevaccinated persons braving the risks which have proved fatal to two such valuable lives as those of the late Professor Freeman and the late Mr Summers. We seem on the threshold of a new experience in the fads of modern civilisation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE following are the lecture arrangements for 1893. On Feb 6th, 8th and 10th Professor C B Plowright will deliver the first of these lectures on the subject of "The Action of Fungi on the Human Body." "Intestinal Parasites belonging to the class Nematoda" will be treated in Professor H J Campbell's lecture on the 20th, 22nd and 24th of February, and the subject of Professor B T Lowne's lectures to be delivered on Feb 27th and March 1st and 3rd will be "The Physiology of the Respiration, Circulation and Nervous System of some Invertebrata." The concluding lectures of this, the first, course will be given by Professor Charles Stewart on Mondays, Wednesdays and Fridays successively during March commencing on the 6th and terminating on the 24th of the month. He will deal with the Physiological Series of Comparative Anatomy in the

Museum of the College. The second course of lectures will be commenced by Dr J Rose Bradford (Arms and Gale Lecturer), who will lecture on May 29th and 31st and June 2nd on "The Physiology of the Kidney." On June 5th, 7th and 9th the subject of the lectures will be "The Pathology of Tumours connected with the Bladder." They will be delivered by Mr J H. Targett, F.R.C.S. (Erasmus Wilson Lecturer). Professor J Hutchinson, jun., will lecture on June 12th, 14th and 16th on "Injuries to the Epiphyses and their Results," and Professor Bernard Pitts, on June 19th, 21st and 23rd, on "The Surgery of the Air Passages and Thorax in Children." The lectures will commence at 5 P.M.

MEMORIAL TO SIR RICHARD OWEN

H.R.H. THE PRINCE OF WALES, as chairman of the Owen Memorial Committee, will preside at a meeting to be held to-day (Saturday) in the rooms of the Royal Society, Burlington House, for the purpose of taking into consideration the most appropriate form of memorial and of appointing a working committee, as well as for the transaction of other business in connexion with the movement. The meeting is called for 11.30 A.M., and will, we doubt not, secure a full attendance.

THE THIRSK DISASTER

WHEN commenting recently on the evidence adduced at the trial of the pointsman Holmes we pointed out that it was the breach of rule and not any defect in the provision made by the company's regulations for dealing with the emergency which had actually arisen to which the accident must be traced. We observe that this same conclusion has been reached by Major Marindin, the officer appointed by the Board of Trade to conduct an inquiry into the circumstances of the accident, as the result of his independent investigation.

BELVIDERE HOSPITAL, GLASGOW

A VERY successful gathering took place under the auspices of the Glasgow Southern Medical Society on the 12th inst., when Dr J W Allan, who has just retired from the office of physician superintendent of the Belvidere Fever Hospital, was entertained at dinner by his professional brethren. Dr Couper, the president of the Society, occupied the chair, and, after proposing the health of "Our Guest," read an address to Dr Allan framed by the Society in which was expressed their high appreciation of his eighteen years' service at the hospital, and of the courtesy which he invariably showed to all seeking his advice and assistance. Dr Allan made an appropriate and feeling reply, and several other toasts followed.

ABATTOIRS

AN abstract is given in a daily contemporary of the report of the London Model Abattoir Society with reference to the spread and working of the public slaughter house system in English and Welsh towns. Forty eight towns in all have obtained powers to raise loans for the provision of abattoirs, and there are other towns, such as Bolton, Birkenhead, Halifax, Leicester, Huddersfield and Manchester, in which abattoirs have been built without recourse to loans requiring the sanction of the Local Government Board. As regards the sale of diseased meat there is, says the report, practical unanimity as to the establishment of abattoirs rendering this practice difficult and almost impossible. It also appears that there is the same unanimous evidence as to the great improvement in the public health and diminution of nuisance which have been found to result from abattoirs. As regards finances, the result in the majority of towns has been success-

ful, and where a slight loss has been experienced this is generally attributed to the continuance of private slaughter-houses side by side with the abattoirs. But the authorities of most towns say that profit was not the object sought for in establishing the system, and that any loss is more than compensated by other benefits. Provincial towns have powers given them for closing private slaughter houses by the Public Health Acts Amendment Act, 1890. In London the County Council, as the licensing authority, has—especially since the passing of the Public Health (London) Act, 1891—absolute control over these licences, except in the case of premises under the authority of the City Corporation.

THE COMMITTEE ON HOSPITALS

A MEETING of the Committee for the final consideration of the recommendations of the Lords' Committee on Hospitals, and with special reference to the recommendation for the creation of a central body to supervise the hospital system with a view to its better working, will be held on Jan 24th. We do not gather that we are likely to receive from this Committee any fully considered suggestions for placing the medical attendance in workhouses on a broader basis. Considering the growth of workhouse infirmaries, the great number of patients they contain and the number of grave diseases which are healed in them, this question needs more definite attention than it has yet received. These infirmaries, too, are centres which afford unrivalled opportunities for the study of many interesting groups of disease.

GLYCOSURIA IN INFANCY

CONSIDERABLE attention has recently been directed to the occurrence of diabetes and glycosuria in young children. Dr Julius Grösz of Prague, writing in the "Jahrbuch für Kinderheilkunde," Band xxxiv, Heft 1, comes to the following conclusions. In certain digestive disturbances there is occasionally present in the urine of infants a strong reducing agent which gives the qualitative tests for sugar, and which is optically active but does not ferment (not answering, therefore to the yeast test). Minute quantities of carbo-hydrates are also found. Dr Grösz never found glycosuria in healthy breast-fed infants. When it did occur there was always some alimentary trouble, most commonly gastro-enteritis. There is often an increase of reducing substances in the urine of infants in addition to the substance referred to above, which is probably either lactose or some product of it. The limit of assimilation of milk sugar in infants is very high, being in healthy, breast-fed children about three grammes and three tenths per kilogramme against one gramme and four tenths in adults. This limit, however, is easily lowered, especially by digestive disturbances, and the glycosuria in such cases is therefore probably due to this lowering of the assimilation limit and partly also to the action of intestinal bacteria.

FOREIGN UNIVERSITY INTELLIGENCE

Berlin.—Dr Adolf Baginsky has been promoted to an Extraordinary Professorship of the Diseases of Children.

Breslau.—Dr Grönouw has been recognised as *privat-docent* in Ophthalmology.

Florence.—Dr A. Lustig has been promoted to the Ordinary Professorship of General Pathology.

Kharloff.—Dr Lomikovskii has been promoted to the Ordinary Professorship of Diagnosis.

Naples.—Drs Zagari and Volpe have been recognised as *privat-docenten* in Medicine, Dr A. Breglia as *privat-docent* in Human Anatomy and Dr G. Corrado as *privat-docent* in Forensic Medicine.

New York (Polyclinic).—Dr W. H. Katzenbach has been appointed Professor of Medicine, Dr A. J. McCosh Professor

of Surgery, Dr Florian Krug Professor of Gynecology, and Dr E B Dench Professor of Otology

Pavia—Dr P Temoli has been recognised as *privat docent* in Operative Medicine.

Prague (German University)—Dr Karl Bayer has been promoted to be Extraordinary Professor of Surgery

Rostock—Dr Christian Lemcke has been promoted to be Extraordinary Professor of Otology and Laryngology

St Petersburg (Military Medical Academy)—Dr S V Shidlovski has been promoted to be Ordinary Professor of Hygiene

Siena—Dr D Morisani of Messina has been appointed to the chair of Clinical Surgery

DEATHS OF EMINENT FOREIGN MEDICAL MEN

THE deaths of the following distinguished members of the medical profession abroad have been announced—Dr L Desnos of Paris, Dr Karl Eichstedt, Extraordinary Professor of Dermatology and Syphilis in the University of Greifswald, Dr Horteloup of Paris

THE works of the Policlinico at Rome have had to be suspended on account of the severe and protracted frost, and the many *employés*, masons particularly, engaged on them have had to apply to the municipality for means of livelihood till operations can be resumed. This is a serious state of matters not only for the workmen but also for the unemployed building itself, which can ill afford such interruption in view of the International Medical Congress which will assemble in its halls on Sept 24th next.

AT the Society of Arts on Wednesday next, Jan 25th, Mr Wyke Bayliss, F S A., President of the Society of British Artists, will read a paper on The Fine Arts in relation to the Sanitary Condition of our Great Cities. Dr B W Richardson will preside

MR. A. SIMS, M B, C M Aber, has been awarded by the French Government the Brevet of Chevalier and the Cross of the Legion of Honour in recognition of his medical services in the French Congo

WITH the consent of Princess Victoria Mary of Teck the new children's ward which is about to be established at the Richmond Hospital is to be named "Princess May's Ward."

THE foot-and mouth disease order of Jan 2nd, prohibiting the removal of cattle from the metropolitan area, has been revoked by the Board of Agriculture.

Pharmacology and Therapeutics.

TETIONAL AS A HYPNOTIC

IN the last number of the *Neurologisches Centralblatt* Dr Brie of Bonn has published a paper on this subject. Tional has similar molecule to sulphonal, which contains, however, three ethyl groups to the two which sulphonal has, while tetional, on the other hand, contains four. It can be obtained at rather less than 2s an ounce. It is a white powder, very insoluble in water at the ordinary temperature, more soluble in hot water and easily soluble in alcohol or ether. It was given to forty two patients in an asylum and was only rejected by one excited maniac, and as he at this time refused food also this has little significance. All the others took it readily, amongst them being some who violently resisted the administration of opium and other hypnotics. Of the patients eleven were the subjects of melancholia and in these a sound sleep of seven to nine hours was obtained with the drug. In the milder cases 1 gramme was sufficient for this, in the more severe ones 2 grammes were

better, preventing a too early awakening. No unpleasant after-effects were experienced even after administration of the drug nightly through several successive weeks. In four cases of melancholia with excitement good results were also obtained, and in the cases of mania—the most severe test of all for a new hypnotic—the results were highly satisfactory. In only one did vomiting follow the administration after a few hours and it was doubtful whether the gastric disturbance was not due to some other cause. Some patients seemed a little tired on the following morning and others complained of an intoxicated feeling after taking it. In cases in which sleeplessness with hallucinations was a marked symptom tional was effective in inducing prolonged sleep and the same effect was observed in cases of psychical disturbance secondary to other disease. In short, Dr Brie regards tional as one of the best and most reliable of hypnotics and he believes it will replace sulphonal. It is almost tasteless, easily administered, quick in its action and without unpleasant after effects.

TEMULIN, THE POISONOUS ALKALOID OF DARNEL SEEDS.

When the seeds of the darnel, *Lolium temulentum*, happen to be mixed with corn various toxic symptoms are liable to be produced in those who eat bread made from it, though some writers have expressed an opinion that these symptoms are not due to the *lolium*, but to something else, such as ergot, which may have found its way into the corn. In order to determine whether *lolium* really contains any poisonous principle Dr Hofmeister of Prague has carried out a series of chemical and pharmacological researches. The symptoms that have been ascribed to *lolium* seeds are of two classes—namely (1) nervous, such as vertigo, headache, contractions, paralyses, illusions, deafness and dark mists in front of the eyes, and (2) gastric, such as nausea and spasmodic pains in the stomach. The cases do not seem frequently to have terminated fatally, the vomiting which was often produced warding off the danger. These symptoms appeared to Dr Hofmeister to indicate the existence of two different toxic bodies, a nerve poison and a local irritant. He succeeded in separating a crystalline alkaloid which he calls temulin, together with two other alkaloids which had been already prepared by other chemists and named by them temulentin and loluin, also some other bodies which did not appear to present any properties of much importance. With temulin, which by the way exists only in very small quantities in *lolium* seed, he made a number of experiments on animals. The lethal dose in cats was 0.25 gramme per kilogramme of body weight. The toxic symptoms were mainly of a nervous character—stupefaction, a staggering gait and paralyses. The respirations were at first quickened and later they became shallow and slow, until death occurred from their arrest. A mydriatic effect was observed in almost all the animals to which temulin was given internally, but when applied to the eye it did not act. This alkaloid appeared to have no effect on the digestive tract, and Dr Hofmeister was able to show that the gastric disturbance caused by *lolium* seeds is due to the fatty matters and fatty acids they contain, for he introduced these substances by means of an oesophageal tube into cats' stomachs and produced vomiting. The bitter substance which is also contained in the seeds has no effect, he finds, on the digestive organs.

SULPHATE OF CODEINE IN THE MORPHINE HABIT

An anonymous writer in the *New York Medical Journal* speaks favourably of the use of codeine in the treatment of the morphine habit. In a case to which allusion is made morphine had been used hypodermically for nineteen months, as much as seven or eight grains daily having been taken for a considerable time, and in which in three weeks from the time the morphine was abandoned the cure was practically complete, and that without the exercise of more than ordinary fortitude and without abstention from daily duties. The writer used a hypodermic injection of one grain of the sulphate of codeine dissolved in hot water, one dose every three hours for a few days, then the intervals gradually lengthened, until on the fourteenth day it was stopped entirely without any difficulty. He recommends before using the codeine the gradual reduction of the morphine to a minimum—say one half or one-quarter of a grain in twenty four hours.

A FERMENT COMMON IN ASCITIC FLUID

It having been suggested by an English surgeon that ascitic fluid, which has the property of changing starch into sugar, has probably some connexion with the pancreas, MM Debray

and Legrun write to *Le Bulletin Medical* that researches which they have been engaged in for a considerable period show that the great majority of ascitic fluids possess the property in question. They have, for example, found it in cases of atrophic cirrhosis of the liver in tuberculous liver, in splenic leucæmia and in hypertrophic cirrhosis of the liver with jaundice. The presence of a saccharifying ferment in ascitic fluid does not therefore appear to them to justify a diagnosis of a pancreatic origin.

UNIVERSITY OF LONDON

MEETING OF CONVOCATION

A MEETING of Convocation of the University of London was held on Tuesday last at the University Building, Burlington gardens, the Chairman of Convocation, Mr E. H. Busk, M.A., LL.B., presiding.

The first business on the paper was the nomination of three persons to be submitted to Her Majesty for the selection therefrom of a Fellow of the University. The following were the nominations—*Alfred William Bennett, M.A., B.Sc., William Job Collins, M.D., M.S., B.Sc., and Henry Greenway Howe, M.S., M.B.* The scrutineers' report showed that Dr Collins had received 855 votes, Mr Howse 642, and Mr Bennett 218. Dr Collins will therefore, in accordance with the usual custom, be selected by the Crown.

Mr W. G. LEMON, LL.B., B.A., presented the report of the annual committee and the scheme for the reconstitution of the University thereto appended (adopted by the annual committee on Dec 9th last). He said that a cry had arisen for a teaching University and there was a feeling that it was not desirable there should be two Universities in London. Nothing could be more fatal to the character of the degrees of this University than that there should be standing side by side with it a University which, if not the University of London, would be a University in London as the degrees of the two bodies would be confounded. Therefore it seemed that any attempt to make a University by a coalition of two or more colleges would be regarded by this University with disfavour. The question therefore arose whether some means might not be devised by which teaching should be associated with this University without the difficulties connected with constituent colleges. The scheme, which was based upon individual representation rather than upon the representation of institutions, was a rough one, laying down principles which, if approved of in the main, could then be clothed with living power. The scheme would in no way diminish the influence of Convocation.

Dr NAPIER seconded the motion, remarking that it would in no way lower the high standard of the degree. The scheme was then formally received.

Mr LEMON moved a resolution approving of the following paragraph of the scheme—"The purposes of the incorporation of the University to be so defined as to include, in addition to the existing purposes, the organisation of regular and liberal education throughout the British Empire, and especially in the metropolis and its neighbourhood, and the advancement of knowledge and encouragement of original research."

Dr NAPIER seconded the motion.

Mr BOMPAS Q.C., said this seemed to him to be an attempt to make one body do two wholly different things. It had been rightly decided that the University should continue to be an Imperial University, and it was therefore impossible that it should also be a municipal University.

An amendment, moved by Dr R. D. ROBERTS, and seconded by Mr E. S. LADBROOK, for the omission of the words 'throughout the British Empire, and especially,' was negatived, and the resolution was agreed to.

Mr LEMON moved the adoption of the following constitution—The University to consist of (1) members (c) Fellows (b) graduates (c) professors examiners, teachers and demonstrators of the University during their respective terms of office. (2) undergraduates. On this the question was raised whether undergraduates should not be included under 'members' and an amendment to that effect was moved and seconded, but was lost, and the original resolution was carried.

Mr LEMON then moved the adoption of the clause in the scheme relating to the constitution of the Senate, on which there was a little discussion.—An amendment to the effect

that Convocation disapproved of a share in the government of the University being given to any who had not undergone graduation was lost, and the original motion was agreed to.—The paragraphs of the scheme relating to Convocation and the teaching staff were also agreed to.—In regard to the latter subject, the scheme provides that the Senate shall have power to appoint members of the teaching staffs of the colleges or other higher educational institutions as professors, teachers and demonstrators, and that although the University must be centralised for certain purposes the teaching of the University shall be given at various centres, according to requirements.

The remainder of the scheme was agreed to with only verbal amendment.

Resolutions were then discussed and agreed to that the annual committee continue to represent Convocation in all matters connected with the Royal Commission, that the Senate be urged to increase the remuneration of the clerk; that the Senate be requested to inform Convocation of the reasons for the rejection of proposals approved by Convocation, and that it be referred to the annual committee to consider a scheme for a degree in connexion with the scientific study of education.

Convocation adjourned after a sitting of nearly five hours.

The following is the

OUTLINE OF SCHEME

FOR THE

RECONSTITUTION OF THE UNIVERSITY

Adopted by the ANNUAL COMMITTEE on Dec 9th 1892, and passed by CONVOCATION on Jan 17th, 1893

I.—OBJECTS OF INCORPORATION

1. The purposes of the incorporation of the University to be so defined as to include in addition to the existing purposes the organisation of regular and liberal education throughout the British Empire and especially in the metropolis and its neighbourhood, and the advancement of knowledge and encouragement of original research.

II.—CONSTITUTION

2. The University to consist of the following—

- (1) Members
 - (a) Chancellor, Vice-Chancellor and Fellows.
 - (b) Graduates.
 - (c) Professors, Examiners Teachers and Demonstrators of the University during their respective terms of office.
- (2) Undergraduates.

III.—SENATE

3. The Senate shall be the executive of the University and consist of the Chancellor and thirty-nine Fellows to be appointed as follows—

I. The Chancellor and seven Fellows to be nominated by the Crown in consideration of a fixed grant from the Treasury three of such Fellows to be nominated in respect of National Museums and Libraries in London.

II. The Chairman of Convocation (ex-officio) and 11 other Fellows to be elected by Convocation.

III. Ten Fellows representing the Faculties of the University and distributed as follows—Arts and Music 3, Laws 1, Medicine 2, Science 2, Divinity 1, Technology 1. (Technology subsequently removed from the Faculties.)

IV. The President of University College, London, the Principal of King's College, London, the Presidents of the Royal College of Physicians of London and the Royal College of Surgeons of England, the Chairman of the Council of Legal Education and the President of the Incorporated Law Society.

V. Four Fellows representing the Municipal Authorities of London—viz. the City Corporation and the London County Council, on condition of an adequate endowment from each authority represented.

4. Members of the Senate other than those appointed under section iv to serve for a period of six years only but to be re-eligible, with provision for the retirement of some members every three years.

IV.—CONVOCATION

5. Convocation to continue as at present and to retain its existing powers, rights and privileges and to include Graduates of the existing University.

6. Convocation to appoint at least two members of each Board of Studies.

V.—TEACHING STAFF

7. There shall be a University Professoriate and a staff of Teachers and Demonstrators.

8. All appointments shall be vested in the Senate and shall be held during their pleasure. The Senate shall have power to appoint members of the Teaching Staffs of the Colleges or other higher educational institutions as University Professors, Teachers and Demonstrators with endowments from the funds of the University on condition that the appointment to such chairs whenever a vacancy occurs should pass to the University.

9. Although the University must be centralised for certain purposes with its own Lectures Laboratories and Libraries, yet the teaching of the University should be given at various centres according to requirements.

10. The National Museums and Libraries to be available for Members and Undergraduates of the University in consideration of their representation on the Senate as provided in paragraph 3, subsection 1.

VI.—FACULTIES.

11. There shall be six Faculties, viz. —

- (1) Arts,
- (2) Laws,
- (3) Medicine
- (4) Science
- (5) Divinity
- (6) Music

Examinations wherein shall result in degrees

All branches of knowledge not qualifying for a degree and not included in any other Faculty shall be included in the Faculty of Arts.

12. Each Faculty shall consist of all the persons for the time being answering the following descriptions —

i. All University Professors in the subjects comprised in their Faculty

ii. Such other Teachers and Demonstrators of subjects comprised in the Faculty as may be recognised by the University

iii. The Examiners of the University in subjects comprised in the Faculty

13. Each Faculty shall appoint—

(a) Members of the Senate

(b) From its own body Members of a Board of Studies

VII.—BOARDS OF STUDIES

14. Each Board of Studies shall consist of Members appointed by the Faculty and two Members appointed by Convocation.

15. The powers and duties of each Board shall be consultative only—viz. (1) to consider and report upon any matter referred to it by the Senate, (2) to represent to the Senate its opinion upon any matter connected with the degrees and examinations and teaching of the subject of its Faculty (3) to deliberate if so requested, in conjunction with the Senate or any Committee thereof, and (4) to meet and act concurrently with any other Boards or Board of Studies on particular subjects.

16. The Boards of Studies shall also advise as to regulations in connexion with Museums Laboratories &c.

VIII.—DEGREES AND EXAMINATIONS

17. The Imperial character of the University to be retained and its examinations to remain open to all Candidates who have complied with the regulations, irrespective of the place or manner of their education.

18. The standard of attainment for matriculation and the various examinations in all the faculties to be maintained at as high a level as at present.

19. Restrictive regulations as to compulsory intervals of time between Matriculation and the Preliminary Scientific Examination and the Intermediate Examination in Medicine and M B Examination to be abolished, provided always that the usual medical curriculum required by the General Medical Council shall have been passed through by a candidate before he presents himself for the final M B.

20. The Examinations in Divinity to be confined to the testing of knowledge and to be in no way concerned with the religious opinions of the Students.

21. The University to have power to grant Certificates or Diplomas as well as Degrees.

22. The University not to have power to grant Honorary or *ad eundem* Degrees, or to allow of procedure to a higher Degree without examination.

23. The University to have power to hold real property and to accept endowments, grants, gifts, devises and legacies, notwithstanding the statutes of mortmain.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE following abstract from the report of the Committee of Management of the two Colleges which was submitted to the last meeting of the Council of the Royal College of Surgeons will be found of interest to those engaged in teaching. The Report was approved and adopted.

The recommendations were as follows —

1. That instruction in Chemistry, Physics, Practical Chemistry and Elementary Biology at the following institutions be recognised as fulfilling the requirements of the new regulations for admission to Parts I and III of the First Examination—viz. The University College of Wales, Aberystwith, the Grammar School, Bradford, and Epsom College

2. That instruction in Chemistry, Physics and Practical Pharmacy in the laboratories of the Pharmaceutical Society be recognised as fulfilling the requirements of the new regulations for admission to Parts I and II of the First Examination

3. That the Liverpool Corporation Fever Hospitals be recognised for the attendance required by Clause 12, paragraph 2, section 1 of the new regulations

4. That the London County Asylum, Binstead, be recognised for the attendance required by Clause 13, paragraph 2, section 1 of the new regulations

5. That the Courses of Laboratory Instruction delivered at University College and King's College be recognised as fulfilling the requirements of the regulations for the Diploma in Public Health

6. That Mr Thomas Cooke's Course of Operative Surgery be recognised as fulfilling the requirements of the regulations for the ensuing year on the same conditions as heretofore.

7. That candidates who desire to present themselves for re examination be required to produce the certificates of additional study fourteen days, instead of three days, before the commencement of the examination, so that the certificates of all students may be in the hands of the secretary at one and the same time.

The Committee also reported the following result of the examinations of the Board for the year 1892 —

1. Under the regulations, dated Oct 1st, 1894, four years' curriculum.

For the first examination in chemistry 664 candidates presented themselves, the percentage of rejections being 34, in Materia Medica 847, rejected 43 per cent., Elementary Anatomy 813, rejected 20 per cent., Elementary Physiology 763 rejected 14 per cent.

For the second examination In Anatomy 819, rejected 35 per cent., in Physiology 924, rejected 45 per cent.

For the final In Medicine 797, rejected 35 per cent., in Surgery 816, rejected 40 per cent., in Midwifery 783, rejected 33 per cent.

2. Under the regulations dated Jan. 1st, 1892, five years' curriculum

First examination In Chemistry 51 rejected 41 per cent., in Practical Pharmacy 29, rejected 31 per cent., in Elementary Biology 10, rejected 20 per cent.

NATIONAL SOCIETY FOR THE EMPLOYMENT OF EPILEPTICS

THERE are few members of the profession who have not been brought face to face with the difficulty of dealing with epileptics capable of work and desirous of employment, and yet prevented by their affliction from finding occupation. It is well known that sufferers from this malady are very often indeed, in the intervals of their attacks, not only able to do useful work, but capable of having their position in life infinitely ameliorated by occupation, especially of a physical kind. In treating epileptics among the well-to-do our aim is to find employment for the sufferers. We send them travelling with medical attendants, we encourage them to take up such work as from circumstances they can engage in, our endeavour is to prevent them from feeling that they belong to a class which must always be liable to find itself cut off from the ordinary business of life. But the difficulty of dealing with persons belonging to other strata of society is enormously increased. They cannot afford the expense of medical or other attendants. They are dependent upon the personal help and the surveillance of immediate relatives, whose time and attention cannot be spent without serious detriment to the money earning capability of the family. If they succeed in obtaining employment in a workshop office, or place of business, the occurrence of a fit of epilepsy throws their employers into alarm, and the unfortunate sufferer is informed that he or she can no longer be retained. The result is that the epileptic is continually finding himself dismissed, often, it is true, with words of sympathy and regret, from a post which he feels himself apart from the occasional attack of incapability, well able to fill. Repeated attempts of this kind are attended with repeated failure, and the unfortunate sufferer gradually drifts into the condition of a pariah, shut off from communion with his fellows, and condemned to a life of idleness and misery. In these classes the end is either the workhouse or the lunatic asylum. Experience of the beneficial results of work upon epileptics belonging to the more favoured classes, for whom occupation of a more or less appropriate character can be secured, would seem to show that, in those less happily circumstanced, the constant strain and worry consequent on the miserable life of forced idleness which they lead tend more and more to the production of a state of mental degradation for which the lunatic asylum is the only resource.

Our columns frequently contain inquiries as to some place at which epileptic sufferers in this position of life can be received. The answers have hitherto been unsatisfactory. It is not a hospital that these persons require. It is the opportunity of useful occupation which they need, together with surroundings in which they may feel that they are not

isolated from their fellows and looked upon with dread or pity, a home is wanted in which they may be actively employed, with the assurance that they are in some measure helping on the work of the world, and in which the occasional occurrence of a fit will not be attended with horror on the part of by standers, or a peremptory dismissal from their employment. A serious attempt is now being made to remedy a condition of things which is fraught with misery to a class of persons entirely free from the charge of having brought suffering of this kind upon themselves. We referred in a recent issue to the National Society for the Employment of Epileptics, which is endeavouring to form a colony in which persons of this class may at length find a haven of rest from the miseries attendant upon their affliction, and we are anxious to again call attention to its efforts because we believe that the medical profession has it in its power to promote powerfully the benevolent scheme.

The idea of the Society is to establish not far from London a colony in which occupation, at first agricultural and after a time embracing other industries, may be provided for epileptics. A public meeting to be presided over by the Lord Mayor, is to be held at the Mansion House on Wednesday next at three o'clock. We hope that many members of the profession, conversant with the need of such an institution, may find it convenient to attend and lend their aid to this project, which has received the sanction of many well known medical men and others interested in helping a sorely afflicted class. The office of the Society is at 20, Hanover square, W.

CHOLERA.

CURRENT NOTES, COMMENTS AND CRITICISM

INCREASING cold and decreasing cholera—or, as many would prefer to say, hibernating cholera—form the substance of this week's intelligence from the Continent. As regards Hamburg three further cases of this disease among the crew of the Spanish steamship *Murciano*, two among the crew of the steamer *Gröthen Böhlen*, recently arrived at the port, and two cases at Pauli have occurred since our last report, also a death from cholera at Schwerin, and the latest official intelligence notifies a fresh case on the 12th inst. One of the cases attacked with cholera was that of a Polish Jew who had recently arrived at Hamburg from London. At a late meeting of the delegates from the German seaports to consider the measures which should be taken in regard to the threatened extension of cholera, we are glad to notice that Herr Ruperti (Hamburg) proposed a resolution for the adoption of the English regulations on the ground that, tested by experience in this country they had been found adequate, without causing unnecessary disruption of marine intercourse.

Intelligence has been received from Berlin of an alarming outbreak having occurred in a provincial lunatic asylum near Halle, in which eight persons have already died, but the disease is believed to have been cholera nostras and not Asiatic cholera. The results of the bacteriological investigations in this case have not yet been promulgated.

From Amsterdam we learn that a fatal case of cholera took place in the person of a man who had arrived there from Utrecht, and from the Hague a fresh case has also been reported. The sanitary condition of Hungary and of its capital, Budapest, has of late attracted attention, and it is certainly such as to call for the prompt application of measures for improvement. The official returns for 1892 show that an epidemic of diphtheria had prevailed in the capital and in twenty five counties and had caused an appalling loss of life, and notwithstanding the extreme cold six cases of cholera had been reported in the space of two or three days at Budapest. It is said that diphtheria and other epidemic diseases are very prevalent in that city at the present time and that the former is again on the increase. It is reported that diphtheria and scarlet fever are also epidemic throughout Servia, and that in Belgrade alone there are over 1000 cases of these diseases, necessitating the closure of the primary and lower middle-class schools. The prevalence of these epidemic forms of sickness during the present cold weather affords an indication of the neglect of sanitation on the part of the municipal and local authorities which may have an important influence on the spread of cholera hereafter. As regards France, there has been little or no

intelligence concerning the progress of cholera in that country, and as there has been no case reported in the weekly bulletins from Paris it may be hopefully inferred that the absence of intelligence is due to there being no cholera cases to report.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6723 births and 5604 deaths were registered during the week ending Jan. 14th. The annual rate of mortality in these towns, which had risen from 20.0 to 29.2 per 1000 in the preceding three weeks, declined last week to 28.3. In London the rate was 30.3 per 1000, while it averaged 26.9 in the thirty two provincial towns. The lowest rates in these towns were 19.5 in Oldham, 20.6 in Newcastle-upon Tyne and in Birkenhead, 21.1 in West Ham and 21.9 in Huddersfield, the highest rates were 31.2 in Preston, 32.4 in Manchester, 32.6 in Salford, 33.4 in Wolverhampton and 36.0 in Bolton. The 5604 deaths included 435 which were referred to the principal zymotic diseases, against 473 and 431 in the preceding two weeks, of these, 122 resulted from measles, 91 from whooping cough, 89 from diphtheria, 59 from scarlet fever, 33 from "fever" (principally enteric), 32 from diarrhoea and 9 from small-pox. The lowest death rates from these diseases were recorded in Huddersfield, Newcastle-upon Tyne, Swansea and Wolverhampton, while they caused the highest rates in Salford, Oldham, Plymouth and Bolton. The greatest mortality from measles occurred in Salford, Manchester, Nottingham, Plymouth, Leeds, Hull and Bolton, from scarlet fever in Plymouth, from whooping cough in Norwich, Birkenhead, Oldham, Gateshead, Nottingham, Bradford and Bolton, and from "fever" in Oldham and Sunderland. The 89 deaths from diphtheria included 61 in London, 4 in Salford, 3 in Manchester, 3 in Sheffield and 3 in Cardiff. Two fatal cases of small pox were registered in London, 2 in Manchester, 2 in Oldham, and 1 each in Bolton, Halifax and Bradford, 56 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 3 in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2973, against 3299, 3254 and 3121 on the preceding three Saturdays, 234 new cases were admitted during the week, against 246 and 202 in the preceding two weeks. The deaths referred to diseases of the respiratory organs, which had been 380, 523 and 953 in the preceding three weeks, further rose to 984 last week and exceeded by 247 the corrected average. The causes of 125, or 2.1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Oldham, Sunderland, Newcastle-upon Tyne and in five other smaller towns, the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Leicester, Salford and Blackburn.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in eight of the principal Scotch towns, which had been 28.5 and 27.1 per 1000 in the preceding two weeks, rose again to 28.5 during the week ending Jan. 14th, and slightly exceeded the mean rate during the same period in the thirty three large English towns. The rates in the eight Scotch towns ranged from 17.3 in Aberdeen and 22.4 in Greenock to 30.9 in Perth and 34.6 in Paisley. The 803 deaths in these towns included 79 which were referred to measles, 11 to diphtheria, 11 to whooping cough, 8 to scarlet fever, 6 to diarrhoea, 4 to "fever" and not one to small pox. In all, 119 deaths resulted from these principal zymotic diseases, against 131 and 146 in the preceding two weeks. These 119 deaths were equal to an annual rate of 4.2 per 1000 which exceeded by 2 the mean rate last week from the same diseases in the thirty three large English towns. The fatal cases of measles, which had been 86 and 79 in the preceding two weeks, were again 79 last week, of which 37 occurred in Glasgow, 14 in Edinburgh, 14 in Dundee and 10 in Leith. The deaths referred to diphtheria, which had been 9 and 10 in the preceding two weeks, further rose to 11 last week and included 6 in Glasgow and 2 in Dundee.

The 11 fatal cases of whooping cough were below those recorded in recent weeks and included 9 in Glasgow. The deaths from scarlet fever, which had been 7 and 17 in the preceding two weeks, declined to 8 last week, of which 5 occurred in Glasgow and 2 in Aberdeen. The deaths referred to diseases of the respiratory organs in these towns, which had been 168 and 212 in the preceding two weeks, further rose to 241 last week and exceeded by 15 the number in the corresponding week of last year. The causes of 61, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 33.4 and 31.3 per 1000 in the preceding two weeks, rose again to 34.6 during the week ending Jan 14th. During the thirteen weeks of the quarter ending the 31st ult. the death rate in the city averaged 24.4 per 1000, against 18.4 in London and 23.9 in Edinburgh. The 232 deaths in Dublin during the week under notice showed an increase of 22 upon the number in the preceding week, and included 7 which were referred to "fever," 3 to diphtheria, 3 to whooping cough, 1 to measles, 1 to diarrhoea, and not one either to small pox or scarlet fever. In all, 15 deaths resulted from these principal zymotic diseases, equal to an annual rate of 2.2 per 1000, the zymotic death rate during the same period being 2.3 in London and 3.7 in Edinburgh. The deaths referred to different forms of "fever," which had been 4 and 11 in the preceding two weeks, declined to 7 last week. The 3 fatal cases of diphtheria exceeded the number recorded in any week since May, 1890. The deaths from whooping cough, which had been 2 in each of the preceding two weeks, were 3 last week. The 232 deaths registered in Dublin last week included 29 of infants under one year of age and 75 of persons aged upwards of sixty years, the deaths both of infants and of elderly persons exceeded the numbers recorded in any recent week. Five inquest cases and 5 deaths from violence were registered, and 83, or more than a third, of the deaths occurred in public institutions. The causes of 22, or more than 9 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF CALCUTTA.

The health officer for Calcutta reports that the total number of deaths registered in the town of Calcutta during the week ending Nov 5th last was 221, against 219 and 218 in the two preceding weeks and lower than the corresponding week of last year by 51. There were 11 deaths from cholera, against 14 and 7 in the two preceding weeks, the number is lower than the average of the past quinquennium by 10. There were no deaths from small pox during the week. There were 11 deaths from tetanus. The mortality from fevers and bowel complaints amounted to 96 and 24 respectively. The general death rate of the week was 24.7 per mille per annum against 25.5, the mean of the last five years. The total number of deaths registered during the week in the amalgamated area of suburbs ending Nov 5th was 138, lower than the corresponding week of last year by 36. There were no deaths from cholera, against 2 and 2 in the two preceding weeks, no deaths from small pox during the week, 12 deaths from tetanus, and the mortality from fevers and bowel complaints amounted to 61. The general death rate of the week was 33.4 per mille per annum, against 40.9, the mean of the past five years. The general death rate of the combined area is equal to 27.4.

THE SERVICES

MOVEMENTS IN THE MEDICAL STAFF

THE following officers have arrived from India in the *Crocodile*. Surgeon Lieutenant Colonel O'Connell and Surgeon Captains Crooke and Kennedy. Surgeon Lieutenant Colonel Anderson has been transferred from Sheerness to the Western district, Surgeon Captain Nash from the North Eastern district to Netley, Surgeon Captain Fayle to Alderney and Surgeon Lieutenant Thompson to Hounslow. Surgeon Captain McLaughlin has arrived home on the completion of a tour of service in West Africa.

Surgeon Captain R. E. R. Morse has proceeded to Sheffield and assumed Medical Charge of the Station

Hospital and troops there, vice Surgeon Captain M. O. D. Braddell, who has been placed on the sick list. Surgeon Captain F. Harris has assumed Medical Charge at Devonport. Surgeon Major R. G. Thomsett, doing duty at the Royal Victoria Hospital, Netley, has been placed under orders for duty in the North Eastern district. Brigade-Surgeon Lieutenant Colonel H. J. O'Brien is under orders to relieve Brigade Surgeon Lieutenant-Colonel J. Maxham, at Barbados, the latter officer returning—tour expired—to England. Surgeon Lieutenant Colonel L. A. Irving has been appointed successor to Brigade-Surgeon Lieutenant Colonel W. T. Martin, in charge of the hospital for insane soldiers at Netley. Brigade Surgeon Lieutenant-Colonel J. H. Hughes is appointed to the Royal Infirmary, Dublin, vice Brigade-Surgeon Lieutenant-Colonel H. J. O'Brien ordered abroad. Surgeon Major General F. W. Wade, Medical Staff, has been appointed Principal Medical Officer, Aldershot, vice Surgeon-Major General Faught.

INDIA AND THE INDIAN MEDICAL SERVICES

Surgeon Captain C. H. L. Palk, Madras Medical Service, is to be Officiating Medical Officer, vice Surgeon Major C. L. Swaine, M.D., who has been appointed to officiate as Sanitary Commissioner, Hyderabad assigned districts. Surgeon-Captain R. J. Baker, M.D. I.M.S. (Bombay), Resident Surgeon, European General Hospital, and Professor of Materia Medica and Pharmacy, Grant Medical College, Bombay, is appointed to be Residency Surgeon. The services of the undermentioned medical officers of the Madras Establishment are placed at the disposal of the Chief Commissioner of the Central Provinces. Surgeon Captain, P. C. H. Strickland and Surgeon Captain W. D. Sutherland. Surgeon-Lieutenant-Colonel B. Evers, M.D., Civil Surgeon, Raipur, is placed temporarily in charge at the Raipur Central Gaol in addition to his own duties. Mr. M. Windross, Officiating Civil Surgeon, Bilaspur, is reappointed assistant to the Civil Surgeon, Jubbulpore. The undermentioned officers of the Army Medical Staff, expected from England for duty in India, have been posted to the Bombay Command. Surgeon Captain R. Kirkpatrick, in succession to Surgeon Captain W. J. Cropton, and Surgeon Captain N. Fruehne, in succession to Surgeon-Captain R. J. A. Durant. Surgeon Colonel W. H. Roberts, M.D., I.M.S., Principal Medical Officer, Secunderabad district, has been granted leave out of India (m.c.) from Nov 8th, 1892, to June 30th, 1893, inclusive. The services of Surgeon Captain H. Herbert, F.R.C.S., have been placed at the disposal of the Political Department for employment on special duty in Kathiawar for three months, on his relief by Surgeon Major W. K. Hatch, M.B., F.R.C.S., and Surgeon Captain J. G. Hojel, M.B., B.S., is appointed, on his relief by Surgeon Captain Child to act as Resident Surgeon, St. George's Hospital, vice Surgeon Captain Baker. The following appointments have been made—Surgeon Captain M. A. I. Collie, M.B., C.M., to be Resident Surgeon, St. George's Hospital, and Surgeon Captain B. B. Gryfoot to be Secretary to the Surgeon General with the Government of Bombay.

NAVAL MEDICAL SERVICE.

The following appointments have been made—Fleet Surgeons. Henry D. Stanstreet to Cape of Good Hope Hospital, Thomas Bolster to Royal Victoria Yard, Deptford, Herbert M. Ellis to the *Victoria*, and John C. B. Maclean to the *Cambridge* (all dated Jan 18th, 1893). Staff Surgeon John A. Collet to the *Collingwood* (undated). Surgeon and Agent Alexander W. Hood at Mullaghmore (dated Jan 14th, 1893), George Sinclair at Kirkwall (dated Jan 18th, 1893).

VOLUNTEER CORPS

1st Essex (Eastern Division, Royal Artillery). Surgeon Lieutenant A. H. Fowler resigns his commission.—7th Lancashire (Manchester Artillery). Surgeon Captain A. I. Chamberlain resigns his commission.—1st Cheshire. Wm. Robert Drizell, M.B., to be Surgeon Lieutenant.—2nd (the Weald of Kent) Volunteer Battalion, the Buffs (East Kent Regiment). Surgeon Captain W. M. Harmer to be Surgeon Major.—1st Volunteer Battalion (the Royal Warwickshire Regiment). James Martin Young, M.B., to be Surgeon Lieutenant.—2nd (Prince of Wales's) Volunteer Battalion (the Devonshire Regiment). Surgeon Lieutenant M. Leamon resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement.—2nd Volunteer Battalion, the Princess of Wales's Own (Yorkshire Regiment). Surgeon Captain R. B. Low to be Surgeon Major (all dated Jan 14th, 1893).—1st Nottinghamshire (Robin Hood) Sur

on Lieutenant-Colonel T Wright resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement.

BRIGADE-SURGEON BENJAMIN COWAN KERR, M.D.,
L.R.C.S. EDIN

Brigade-Surgeon Kerr, Army Medical Staff, who died at Clifton on Jan. 3rd, gained his appointment as Assistant Surgeon in 1855 and in 1871 was promoted to the rank of Surgeon. Two years later he was made Surgeon-Major and in 1882 Brigade-Surgeon. He took part in the Kafir War of 1879 and 1880, and retired in 1889.

"KNOWLEDGE IS POWER."

Naval medical officers have of course their own duties to perform, but it occasionally happens that they are able to render effective aid and good service outside their own immediate sphere of duty, of which the following may be taken as an instance. H.M.S. *Pallas* got ashore in November last in one of her recent exploratory visits to the Pescadores, owing to a tidal current having suddenly swung the ship round on a shingly part of the eastern reef, from which, however she subsequently got off without sustaining any appreciable damage. We learn from a correspondent writing from South Formosa to the *North China Herald* of Dec. 9th last, that a sailing cutter was sent off from the *Pallas* in charge of Staff Surgeon Gipps R.N., to Makung in search of aid and that, owing to a heavy sea, the crew of the cutter had a very exciting time of it. The natives of the islands to the north and windward of the *Pallas* came out in their large fishing-boats and the steam tug *Samson* also went to the assistance of the *Pallas*. The steam tug unfortunately also got aground for a time on one of the soft coral reefs. Staff Surgeon Gipps, owing to his knowledge of how to make use of the naval semaphore and Morse signals, is stated to have rendered most effective aid on the occasion by his unflinching zeal and ability in conveying orders between the two vessels.

FIRE AT DEVONPORT MILITARY HOSPITAL.

An alarming fire broke out early on the morning of the 17th inst. at the Military Hospital at Devonport and destroyed one of the five blocks of that building. The hospital was full of patients at the time, but all were removed from the burning portion to a place of safety. At the top of the block there were five serious cases. The supply of water was at first insufficient, but when more water was obtained the fire brigade and naval authorities were able to cope with the outbreak. The fire, which broke out in the top storey and spread to the second, was got under control about seven o'clock. Its exact cause has not yet been ascertained, but it is believed that the fire arose from an overheated iron pipe from the stove having ignited the woodwork of the ceiling.

THE DEATH OF LIEUTENANT D B ELPHINSTONE, R.E., AT THE EUROPEAN GENERAL HOSPITAL, BOMBAY

The *Times of India* gives a long account of the sad accident which occurred to this officer and resulted in his death on Dec. 28th at the time he was a patient in the European General Hospital. It appears that Lieutenant Elphinstone, R.E., was admitted to the hospital suffering from a severe attack of malarious fever on Dec. 25th, 1892. He was placed in one of the wards on the top floor of the new building in which there were several other patients at the time. He seems on the 28th ult. to have left his bed during the brief absence of the nurse from the ward and to have thrown himself from the hospital corridor to the ground below. He died about two hours afterwards of ruptured spleen and abdominal injuries.

Correspondence.

'Audi alteram partem.'

INNERVATION OF THE PALATE

To the Editors of THE LANCET

SIRS,—No notice appears to have been taken in THE LANCET of Jan. 14th of No. 2 of the series of cases of facial palsy in children recorded by Dr George Carpenter on Jan. 7th, in which the soft palate was said to be paralysed on one side. As none of the leaders in neurology have commented on this case, will you kindly allow one of the rank

and file to offer a few remarks. At the beginning let me say that Dr Carpenter's case is a very unconvincing one, he does not state whether the palate moved on mechanical stimulation, he does not even say whether this test was applied. Secondly, the tonsils had both been partially removed before her attack of scarlet fever (presumably for chronic hypertrophy) and the left one is stated to have been enlarged on her return to the Evelina Hospital. I suppose this tonsil was in a condition of subacute inflammation.

In the article on Tonsillitis in "Fowler's Dictionary of Practical Medicine," Dr de Havilland Hall writes "If fluids are taken, they frequently return by the nose." It is now well known that post-nasal growths frequently coexist with enlarged tonsils, possibly they were present in this case. I believe I am correct in saying that in some cases of post-nasal growths liquids return by the nose during swallowing. This symptom simply shows that the soft palate has not properly shut off the nasal cavity from the pharyngeal. I admit that palsy of the palate is the commonest cause of this but any local condition of swelling growths &c. may so interfere with the proper coördination of the muscles concerned in the act of swallowing that nasal regurgitation may occur. I venture, therefore, to demur to Dr Carpenter's statement that "the fact that fluids returned through the nose shows unmistakably that there was paralysis." In connexion with this subject let me briefly refer to a case of diphtheria which was under my care two years ago. A girl of fifteen, whose younger sister had just had a very mild attack of diphtheria in the same house, was seized with the disease in that severe form in which most of the stress of the complaint falls on the nose and naso-pharynx, there was also extreme swelling of the throat and neck, rendering examination and local applications difficult of performance. Quite early in the course of the disease (in the first week) fluids sometimes returned through the nose during swallowing. Throughout her illness I could find no palsy of the face, accommodation, or limbs (motor or sensory), her knee jerks were normal and equal on the two sides to within one hour of the time of her death on the nineteenth day. It is interesting, as bearing on this question of palsy of the palate, that as the swelling of the throat subsided, together with the offensive sanious nasal discharge, her power of swallowing improved, though her general condition became steadily worse. Surely if in this case the palate was paralysed, this should have continued and become complete while her illness was going on steadily to the fatal termination by cardiac failure.

To conclude, Dr Carpenter has not, in my opinion, proved that there was unilateral palsy of the palate in his case. It is a difficult thing to prove that two such authorities as Drs. Hughlings Jackson and Gowers are wrong in their observations on the innervation of the soft palate, moreover, the experiments of Dr Beever and Professor Horsley are, I believe, generally regarded by physiologists as having definitely proved that the levator palati is supplied by the accessory nerve to the vagus. Any cases related in order to overthrow these conclusions from clinical and experimental work ought to be so accurately and fully reported that there is no serious omission as to the tests applied in their investigation.

I am, Sirs yours truly

LEONARD J KIDD M.D. BRUX. &c

George street Hanover square W., Jan. 17th 1893

CAPE LUNACY PROCEEDINGS

To the Editors of THE LANCET

SIRS,—I was under the impression, prior to reading a cutting from a local paper called the *Cape Argus* that no person could be pronounced of 'unsound mind,' consistently at any rate, by any judge without the support of medical testimony. I do not suppose any British jury would venture to return such a verdict unsupported by special expert evidence, but the extract I send clearly shows that I labour under a false impression—a sort of delusion, I suppose. Although the lay report may not be altogether reliable, it seems sufficiently clear perhaps for me to venture to point out to you that here a young man has been permitted to deal with his property up to twenty nine years of age—his brother's testimony goes to establish that this young man has been spending money in a somewhat reckless manner, running up accounts and signing bills. Only very recently has this young man shown any signs of violence, then it seems only one sign has been proved. The excuse advanced for depriving this young man of the enjoyment of his estate is that

"he might get better if the financial worry which was now troubling him was got rid of." On the other hand, this excuse seems to suggest that he has been actively engaged in financial undertakings. However, without medical evidence, judging by this lay report, this young man, you will observe, is pronounced of unsound mind and placed under restraint without the usual medical certificates. Of course you will accept the fact that the learned Chief Justice merely followed the powers vested in him by the Lunacy Act in force in this colony, but in this particular example it seems very hard to be able by "law" to deprive a British subject of property and liberty upon what appears to be in complete evidence. Although the learned Chief Justice adds the comforting remark "that it would always be competent for him, should he become sound of mind, to apply to the Court for his discharge," there might be a better prospect perhaps of this advice being consummated if the sufferer were placed in an asylum instead of being left with his friends, when it is alleged he has been growing worse from ten to twenty nine years of age. Possibly this is a hopeless case. In an asylum his chances of recovery would be greater, if we take for example the case of a lady who was declared of "unsound mind" after the usual manner and duly placed in an asylum, where before a month had expired she appeared before the Court and was declared to be of "sound mind."

I am, Sirs, yours truly,

Cape Colony, Dec. 23rd, 1892. S CARTWRIGHT REED, M D

THE NEW MEDICAL BILL FOR NEW SOUTH WALES

To the Editors of THE LANCET

SIRS,—As a copy of this Bill has lately been forwarded to me I should like to bring a few of its defects before the profession in Australia. The Bill provides for the formation of a Medical Council, to consist of ten practitioners, five of whom are to be appointed by the governor of the colony and five by the Senate of the University of Sydney. I would point out that no direct representation is given to the profession on the Council and, further, that no arrangement is made for the payment of members of the Council. It is to be hoped that, if the Bill has not yet passed, two clauses will be introduced providing for the election of direct representatives and for the payment of members. To me it seems strange that in New South Wales the payment of members is not provided for, especially so because in the Health Act, 1890, of the Colony of Victoria (which has provided for the formation of a Board of Health and a Minister of Public Health) full arrangements have been made by Section 11 for the paying not only of travelling expenses but also for attendance. I would further suggest that New South Wales should follow the example of Canada, and introduce a clause providing for the prosecution of unregistered practitioners. Hoping practitioners will accept these few hints,

I am, Sirs, yours truly

Liverpool.

ROBERT R. RENTOUL.

"THE DRAINAGE OF MIDDLE-CLASS DWELLINGS HOUSE-TO-HOUSE VISITATION"

To the Editors of THE LANCET

SIRS,—If you can carry the question of house to house visitation the country at large will be deeply indebted to you, for it must tend very materially to lessen the amount of zymotic disease. At the present time not only do sanitary defects which require very careful examination to detect remain uncorrected, but those also are neglected which are patent to the meanest scientific observer, and as a consequence lives are being daily sacrificed which with a proper amount of sanitary supervision might be preserved. I know of houses some built but a very few years ago, and not very far removed from my own residence, with ventilating shafts about a quarter or half the diameter they should be and opening only just above the bedroom windows, while in others the house drains were originally neither laid on concrete nor were they properly jointed. We have lately had an inspector deputed by the Surrey County Council to examine the system of main drainage in this district, but it would have been far more satisfactory if the house drainage had received more atten-

tion, inasmuch as zymotic disease arises more frequently from the latter being defective than from the other. If the latter be perfect we can await, as you say, the advent of cholera at any rate, without fear. I am told that house-to-house visitation is already in force at Brighton and has been productive of much good. But in order that defects may be detected we want three things: (1) properly qualified medical officers of health unconnected with private practice, (2) properly qualified inspectors of nuisances, (3) properly qualified plumbers. Without these three requirements being fulfilled the work cannot but be done very imperfectly. I would further suggest: (1) The report of every inspection made by the inspector of nuisances should be daily made to the medical officer of health, (2) no sanitary work undertaken by any plumber should be allowed to pass unless it has undergone inspection by the medical officer of health or sanitary inspector.

In course of time sanitary law will no doubt be more perfect than it now is, and the present Secretary of the Local Government Board ought to render effective service in this particular.

Surbiton, Jan. 16th, 1893.

I am, Sirs, yours truly,

F P ATKINSON.

P S.—The ventilating shafts attached to the houses between Earlsfield Station and Clapham Junction require, I think, the sanitary inspector's attention. They are a good example of the size sometimes allowed.

DEATH UNDER CHLOROFORM

To the Editors of THE LANCET

SIRS,—Dr Hill's revelation and Mr Edgelow's version of the cause of death, published under the above heading in your issue of Dec 10th, 1892, do not remove but add to the existing confusion in the matter of "the safe administration of chloroform." These letters lead to the question, What is "the open method of administering chloroform" which teachers in anaesthetics recommend as the safest to employ? If one method is called the open method, there is probably also a closed method. Some of your readers will probably be so kind as to give, through THE LANCET, the desired correct information of the meaning of these terms, which cannot fail to be of the highest interest. No one will doubt that as long as the respiration of a patient under chloroform remains normal and regular there can be no danger. Yet we are told in the records of fatalities under chloroform that the respiration was watched with the utmost vigilance from start to finish. There then remains no other explanation but that the method of administration employed must be at fault which permitted the intake of too concentrated vapour causing a too rapid effect on the system, intensified by the existence of residual concentrated vapour in the lungs which probably accounts for the sudden and irremediable death. The lesson drawn from such accidents is. Commence in every case, of whatever age and condition the patient may be, the administration of chloroform with vapour very much diluted, and gradually and systematically increase the strength of the vapour to the strongest the particular patient is able to inhale with normal and regular respiration. The first gasp or irregularity in the respiration must be taken as the first and only sign of approaching danger. If this is at once corrected, as it can be by lessening the strength of the vapour, no more harm can follow such occasional gasps under chloroform than we expect to follow the gasps we constantly are compelled to make in ordinary life during speaking, singing

¹ For the administration of chloroform no inhaler is needed but a piece of lint folded two or three times a cambric handkerchief, or piece of linen will answer every purpose. A convenient form of inhaler consists of one which has the advantage of economising the chloroform consisting simply of a piece of flannel stretched across a wire frame supporting a small piece of sponge. The anaesthetist should provide himself with a drop bottle holding at least an ounce and should have a supply of three or four ounces in reserve if necessary. Having sprinkled the lint or inhaler with a small amount of chloroform, it is turned moist side down towards the patient's mouth. At first it should be held about an inch away, and as the chloroform evaporates should gradually approach the mouth. As the moisture disappears fresh chloroform should be added. The aim of the administrator is to allow air to freely enter the patient's lungs mixed with about 5 per cent. of chloroform vapour as soon as the agent begins to take effect the patient, especially if addicted to alcoholism begins to struggle. It is not wise to forcibly restrain him except to prevent damage being done either to himself or to those around. It is well to remember that the more continuously chloroform is administered at this stage the less the patient struggles. Children usually cry, and in the deep inspirations which ensue a large amount of vapour is taken in.—Copied from a most recent edition of "Guide to the Administration of Anaesthetics."

r muscular exertion No other of the usual and alarming signs of danger need be looked for—they cannot occur

I am, Sirs, yours truly,

HEALTH

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Small pox Epidemic

THE one thing uppermost in men's minds at the present time is the prevalence of small pox in this city, which has recently increased to such a degree as to deserve the title of epidemic. The reported cases, which, according to the official reports had increased during the four preceding weeks from 12 per week to 21, suddenly increased last week to 67 and since then the disease has continued to spread. The distribution of the attacks is still very general, for of the eleven registration subdistricts which together constitute the city, not less than ten have furnished one or more cases of small pox during the last fortnight. Cases have been received from Her Majesty's Prison, from the Workhouse Casual Wards from the out patient department of the Royal Infirmary, and from several of the largest common lodging houses in the city. Such being the distribution of infection in Manchester, and its spread having been so steady and progressive during the last five or six weeks, there seems every likelihood that we are on the eve of a very serious epidemic of small pox. It is reported that yesterday a tramp was found to be suffering from small pox at a large common lodging house. The inspector visited him and after making arrangements for his removal left the house. As soon as his back was turned the man bolted through the streets and was temporarily lost sight of. After the lapse of some hours the patient was captured and his removal to hospital was effected, but not until he had almost certainly infected a considerable number of his fellows. At last the Corporation seem to have become convinced of the necessity of providing adequately for the isolation of small pox cases in Manchester. Cases have been sent to Monsall so rapidly of late that the hospital is within measurable distance of being full, and if additional arrangements had not been set on foot within the last few days the Corporation would have been in the undignified position, before many more days had elapsed, of having to confess themselves unable to cope with an epidemic which, at present at any rate, is of but moderate proportions. For some weeks past they have been making inquiries for suitable sites, but of course they have had great difficulty in persuading land owners to submit to the establishment of a small pox hospital in their neighbourhood. It is rumoured that with respect to one site at the south side of Manchester legal proceedings have already been instituted in order to prevent the Corporation from utilising land at present in their possession for small pox hospitals purposes. In one direction, however, the Corporation are evidently proceeding on right lines. Recognising the fact that Monsall Hospital will soon be full, they are now erecting temporary pavilions on a large plot of ground contiguous to the present hospital, and they hope to have one or more of these pavilions ready for occupation by the end of the present week. They are also making arrangements to completely separate the small pox hospital from the hospital appropriated to the several "fevers," and are surrounding both establishments with a fence of suitable construction. They are doing even more than this, for they have taken steps to adapt some large buildings in their possession, in a part of the city not far removed from Monsall, to the purposes of a convalescent hospital, so that as soon as the patients have so far recovered at Monsall as to render their removal a safe proceeding they will be sent in the hospital ambulances to the house of recovery as it is called, which building, it is hoped, will be ready for their reception in the course of a very few days. Hitherto the type of the disease in Manchester has not been severe. Several bad confluent cases have been observed and some of them have died, but the attacks have been for the most part fairly mild, and up to the present time the case fatality has been decidedly low.

Vaccination and Revaccination

In the course of last week Dr Hubert Arey paid a visit to Manchester on behalf of the Local Government Board, with the object of inquiring into the administration of the Vaccination Acts in the township of Manchester. The guardians of all three of the unions which are contained in the city are fully alive to the necessity of bestirring themselves and their officers for the vaccination and revaccination of the people. In all three of these areas placards have been issued drawing attention to the desirability of vaccination and revaccination and offering additional facilities for the performance of the operation free of charge to the public. It is disappointing to hear that hitherto, at all events the people of Manchester have not availed themselves to any appreciable extent of the facilities which have been so freely offered. The better class of the community are protecting themselves in large numbers, but the poorer classes, who are exceptionally exposed to infection, seem to be utterly careless and to treat the recommendations of the guardians and of the Corporation with simple indifference.

January 17th.

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

General Hospital.

SOME important changes in the internal administration of this institution have lately come into operation. Hitherto it has been customary for the patients to provide their own cutlery, crockery, tea, coffee and sugar with periodical supplies of clean linen. This custom has been found to be attended by many inconveniences and abuses, and it is now proposed that the institution should find all these things except the linen. Of course a financial burden will be imposed upon the hospital, but the patients and the officers of the hospital will reap the benefit. The contraband articles of all and indiscriminate kinds smuggled into the wards by invidious and indiscreet friends will now gradually decline, and, it is to be hoped, become a reminiscence of bygone times. The infinite harm and injury done by this abuse is well known and has always been difficult to combat.

The Queen's Hospital

An innovation at this institution, the result of which remains to be proved by time, is the subject of some criticism. It is proposed on Feb 1st to charge an additional registration fee to those who have once passed through the casualty room. The object is to check the abuse by those who can afford to pay and who come mainly with injuries and complaints of a trivial character. A large number of these come from the locality in which the hospital is placed and may reasonably be treated quite as well at home by practitioners in their own neighbourhood after the first visit to the hospital. Thus whilst the General Hospital increases its obligations by providing for the patients the Queen's Hospital seeks to improve its finances by charging a small fee to certain of those patients who need, it is said often unnecessarily, its assistance.

Hospital for Women

A vacancy has occurred in this institution by the resignation of Mr Lawson Tait. Already there are several candidates in the field anxious to place their services at the disposal of the hospital.

January 18th.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Sight Tests for Railway Servants

A MEETING of railway servants, largely attended, has been held at Gateshead to protest against the introduction of the new eyesight test. The men do not object to tests but to the testing methods adopted. For instance, they object to wool being used, and say that it is more adapted to young ladies going to Berlin wool stores and not for practical men. They have no objection to being tested by the signals and lights which they are accustomed to see and work with night and day but very strongly object to alphabets and coloured wools.

Elswick Workmen and Newcastle Medical Charities

The workmen of Sir W G Armstrong, Mitchell and Co at Elswick have contributed during the past quarter the large sum of £324 to various Newcastle medical charities. The bulk of the money goes to the Royal Infirmary, while about £100 is distributed amongst the minor charities.

The Queen's Nursing Association at Darlington

The first annual meeting of the Queen's Nursing Association has been held at Darlington and the report was highly satisfactory. The mayor, who presided, and other prominent persons, including medical men, spoke highly of the work of the Association.

Illness of the Medical Officer of Health of Sunderland

I regret to have to state that Mr Wood, formerly police surgeon for Sunderland, and now medical officer of health, is suffering from scarlet fever. Together with two of his children Mr Wood has been removed to the new infectious diseases hospital. The latest accounts of Mr Wood's and his children's condition is good.

The Small-pox Epidemic in the North.

Small pox has now assumed an epidemic form, indeed, there are not many towns in the northern counties free from it. Cases have been notified at Sunderland and at Houghton le Spring, about six miles from Sunderland, and the disease has been lingering in the Northallerton district for some time. An outbreak is also reported at Durham County Prison, where there are several cases. At some of the colliery villages near the city of Durham cases have also been noticed.

Lectures on Nursing at Carlisle

A course of lectures on Sick Nursing has just been commenced at Carlisle under the auspices of a committee of ladies. Dr Lediard is the lecturer, and his syllabus of the eight lectures which he proposes to give show that they will be of a thoroughly practical and useful character. Each lecture is illustrated by demonstrations in which nurses of the Carlisle Infirmary take part. We understand that upwards of 300 women of all ranks have joined the class, and there can be no doubt of its value and importance.

Newcastle-on Tyne, Jan 17th.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

Health of Aberdeen

THE returns of zymotic cases last week were Measles, 36, scarlet fever, 11, diphtheria, 8, typhoid fever, 6, erysipelas, 12 total cases, 73, being an increase of 6 as compared with the previous week. The number of cases of measles continues to decrease, the increase being in erysipelas and diphtheria. Dr Hay reports two deaths from influenza in December, as against one in the previous month and 21 in December, 1891. Influenza is undoubtedly present in the city, but it is of a less serious type than in previous visitations.

Aberdeen. A Year's Work in the Sanitary Department

The sanitary inspector reports that during 1892 the number of nuisances registered was 6169 and the number abated 5593, 936 patients were removed to hospitals, 6706 supervised at home, 6704 houses &c. disinfected after infectious diseases and 1052 sets of infected bedding and clothing disinfected and washed. There were 124 seizures of unwholesome food, comprising 18,985 lb of beef, 306 lb of mutton, 12 lb of tinned meat, 7½ lb of ham, 168 lb of offal, 41,955 lb of wet fish, 224 lb of dried fish, 2016 lb of smoked fish, 990 lb of fruit, 64 lb of jam and 27 lb of bread, the total weight being over 28½ tons. The fines amounted to £6715s 6d.

Aberdeen Ambulance Association Classes

A meeting was held last Saturday for the purpose of making arrangements for the formation of ambulance classes under the auspices of the above Association. Over 400 people were present, including a detachment of city police. Rev James Smith, St. George's in the West, presided and gave a brief introductory address, followed by Chief Constable Wyness. In the absence of the lecturer, Dr Riddell, through illness, Dr M'Gregor took his place and explained the object of the lectures. Mr William Smith, advocate, secretary of

the Aberdeen Ambulance Association, explained the system on which certificates were granted and, in closing, made strong appeal to the public for funds to enable the Association to carry on its good work.

Public Health

Matters are not mending in Glasgow so far as small pox concerned, there being now (Tuesday) 42 cases and treatment. We have had Dr Sidney Coupland, the representative of the Royal Commission on Vaccination, in Glasgow for some days making inquiry into the manner in which the authorities are endeavouring to meet the epidemic. Dr Russell's report contains some very instructive examples the ways in which the disease is spread.

January 18th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

National Children's Hospital, Dublin. Albert Victor Memorial Bed

ON Saturday last his Excellency the Lord Lieutenant opened the Albert Victor Memorial Bed in the Children's Hospital, Harcourt-street. An address having been presented to his Excellency, he declared the memorial bed dedicated to the use of the suffering and to the memory of the Royal Highness Prince Albert Victor, Duke of Clarence and Avondale. Over the cot hung a portrait of the deceased prince bearing an inscription to the effect that it was presented to the hospital by their Royal Highnesses the Prince and Princess of Wales. A brass shield at the head of the bed bore the following inscription: "In memoriam Albert Victor Memorial Cot. Founded in memory of H.R.H. Albert Victor Christian Edward, Duke of Clarence and Avondale, K.I., K.P., Major of the 10th Royal Hussars. Born Jan. 8th, 1884. Died Jan. 14th, 1892. Supported and endowed by subscriptions from some of Her Majesty's subjects in Ireland as a tribute of loyal affection and regard, this bed was publicly opened by His Excellency Baron Houghton, Lieutenant of Ireland, Jan. 14th, 1893."

Barrington's Hospital, Limerick.

The Sir Croker Barrington Memorial Committee have reported that a field adjoining the hospital has been enclosed, laid out as a recreation ground for the patients, also the portion of the hospital formerly occupied by the city dispensary has been fitted up as private wards, three in number. The total expenditure in carrying out these works came £486 18s 5d. During the past year 539 patients were admitted into the wards of the hospital and 2917 persons were treated as extern patients. By the demise of Mr Michael Riordan hospital lost an upright and trustworthy physician. It has been decided by the committee to discontinue as unnecessary the employment of probation nurses from the Dublin Nursing Institution, and in future to train their own nurses, so as to be provided with a staff of trained nurses for the hospital who would also be available for private cases when required. Towards the expenses of the institution the Corporation of Limerick contributes an annual grant of £300.

Ashford Testimonial

This week there will be placed in position a memorial in Irish granite of the late Mr Ashford, who for many years lived at Ball's Bridge, near the city, and who had so endeared himself to the poor of Ringsend and neighbourhood that they subscribed the necessary funds for a memorial of his charitable deeds. One side of the monument bears the following inscription: "Erected January, 1893, by public subscription, to commemorate the memory of Dr W. Ashford for the valuable services he rendered for a period of half a century to the poor of St. Mary's parish."

Mr Callaghan, late visiting physician to the Cork Union Workhouse, has received a retiring allowance of £75 a year.

Dr Norman J. Townsend has been elected medical officer to the Cork Protestant Fellowship Society.

The Belfast Hospital for Consumption and Diseases of the Chest

The annual meeting of this charity was held on Jan 11th. There were during the year 864 extern and 50 intern patients. Mr D. C. Stack has been appointed surgeon in place of Mr McKisack, resigned. From the balance sheet it appears that there is a sum of over £18 in hand. The building fund was

1869 15s. 2d., out of which the lands for the site of the new hospital &c. had been purchased, leaving a balance to the credit of the fund of £2352 2s. 4d. There was a total investment in the Endowments account of £1205 9s. 6d.

The Belfast Medical School and the Royal University

I understand that a memorial has been sent to the Senate of the Royal University by the students of the Belfast Medical School in which they state that, owing to the resignation of Dr. Swann of Dublin, a vacancy has occurred in the list of medical examiners of the Royal University, and although on average of about 50 per cent. of the medical students of the University have received their professional education in Belfast, yet out of the ten examiners at the degree examination there is only one from that city. The students therefore ask the Standing Committee of the Royal University to consider this very inadequate representation of the Belfast School of Medicine on the Board of Examiners and to forthwith elect to appoint a Belfast ophthalmic surgeon to the vacancy. The petition is signed on behalf of the Belfast students by Dr. Morrow, president, and by Mr. T. Houston, B.A., the secretary of the Belfast Medical Students Association. I understand that two Belfast gentlemen are candidates for the post of examiner in ophthalmology—Dr. J. Walton Browne, who is Senior Surgeon to the Royal Hospital and Ophthalmic Surgeon to the Belfast Ophthalmic Hospital, and Dr. Nelson, who is Ophthalmic Surgeon to the Royal Hospital and to the Belfast Hospital for Sick Children.

The Belfast Hospital for Sick Children

At an election of medical officers held last week Dr. Stack was appointed surgeon and Dr. S. B. Smyth assistant surgeon.

Proposed Clinical Instruction at the Belfast Workhouse

At a meeting of the Board of Guardians held on Jan. 17th a resolution was moved by one of the members that the resolution approving the proposals submitted by Professor Curran of giving clinical lectures to medical students in the infirmary and hospital of the workhouse be rescinded, but after a very lengthened and heated discussion it was lost eleven voting for and fourteen against it. The question is now in the hands of the Local Government Board.

January 18th.

BERLIN

(FROM OUR OWN CORRESPONDENT.)

The Berlin Medical Society

THE Berlin Medical Society held a general meeting in the Langenbeck House on the 11th inst. The number of the members has risen to 873. Professor Virchow was re-elected President by 139 out of 145 votes, three being given to Professor von Bergmann and three to Professor von Bardeleben. Professor Virchow accepted the office with thanks, but gave it as his opinion that the assembly should consider future circumstances as the only course he could steer was the old one. The assembly declared by applause that it was satisfied with the old course. The other members of the Managing Committee—Drs. Bergmann, Herroch, E. Fränkel, Senz or Korte, Falk and Abraham—were also re-elected. Professor Virchow alluded in warm terms to the late Privy Counsellor Dr. Hollstein and his "Manual of Anatomy," which he (Professor Virchow) still used as a book of reference.

The Transport of the Sick and the Dead

Arrangements have been made for instantly securing the assistance of the fire brigade for the transport of the sick and the dead in case of any severe epidemic in Berlin.

A New Professor of Anatomy at Würzburg

Professor von Lenhossek of Bale has been called to the University of Würzburg to succeed Professor Armin Fick, who is going to Leipzig.

Dr. Felix Hirschfeld

Dr. Felix Hirschfeld, assistant in the medical department of the hospital at Moabit, has established himself as a private lecturer on internal medicine in the university here. He has already gained himself a name in medical science by his researches on assimilation and nutrition, published in Pflüger's Archiv. Virchow's Archiv. Dr. Felix Hirschfeld

Archiv (Clinical Weekly) and Das Centralblatt für Medizin (Central Medical Journal)

Professor Bernhard Fränkel

Professor Bernhard Fränkel has been elected an honorary member by the Italian Society for Laryngology.

Cholera in Hamburg

Eleven cases of cholera appeared in Hamburg last week. January 15th.

PARIS

(FROM OUR OWN CORRESPONDENT.)

A New Hypnotic

IF in these high pressure days insomnia has become, with its congener, neurasthenia, a *maladie à la mode*, therapists and chemists cannot be accused of lack of enthusiasm in the search for fresh remedies for that distressing condition. The latest addition to the list of hypnotics has been christened by its discoverers, M. Hanno and Ch. Richet, "chloralose." These physiologists, in the course of their search for chloral compounds that in decomposing in the system give up their chloral gradually, found that contrary to their expectations lactic chloralide possessed no hypnotic properties its toxicity however being very marked, the untoward symptoms consisting of epileptiform attacks, together with abundant bronchial secretion and consequent asphyxia. A combination of chloral with glucose-anhydrous chloral, otherwise chloralose—yielded excellent results. It is prepared as follows: Equal parts of anhydrous chloral and dry glucose are mixed together and heated to 100° C. for an hour. The thick mass left on cooling is treated with a little water and then with boiling ether. Water is added to the part soluble in the ether and the mixture distilled five or six times with water until no trace of chloral is discernible. Repeated crystallisations of the residue give a compound α (only slightly soluble in cold water, but fairly soluble in hot water and in alcohol) and a compound β (soluble with difficulty even in hot water). The yield of the α -compound is about 3 per cent. It crystallises in fine needles, melting at 164° to 165° C., its formula being $C_{12}H_{22}Cl_2O_6$. Treated with caustic potash it yields no glucose. The β -compound or parachlorose crystallises in pearly plates, melting at 229° C. This latter substance was found to be inactive. Chloralose, on the contrary, possesses the apparently contradictory properties of acting as a hypnotic and of augmenting at the same time the excitability of the spinal cord. As much as 60 centigrammes per kilo of body weight of it can be given to dogs without involving a fatal result, but anaesthesia is marked. It begins to manifest its hypnotic effects at 2 centigrammes per kilogramme, being in this respect much superior to chloral, which is inactive at that dose. This proves that chloralose does not act in virtue of the chloral set free after ingestion, since 2 centigrammes of chloralose cannot yield more than 1 centigramme of chloral. The discoverers then tried its effects on themselves beginning with doses of 5 centigrammes and pushing on to 75 centigrammes. No toxic effects were produced, but hypnotic results were observed with doses of 30 centigrammes and over. Drs. Landouzy and Montard Martin have for the space of five months used it clinically in cases of obstinate insomnia. They report that it can be administered in doses not exceeding 60 centigrammes, without producing any digestive trouble, headache, or other inconvenience on waking. It is best given in doses of from 20 centigrammes (minimum dose) to 75 centigrammes. Its solution being very bitter, it is probably best administered in cachets.

Académie de Médecine

The average Briton is apt to understate the distinction conferred by the red ribbon or rosette of the *Légion d'Honneur* and yet very few Frenchmen of any standing can be said to be perfectly happy before they can sport the said ribbon in their button holes. When I state that in no country is our own profession awarded its just quota of honours I shall find few bold enough to contradict me. In France a considerable number of practitioners take part in public life as senators, deputies, mayors and municipal councillors or mayors and quite a large proportion of them belong to the premier order of the *Légion d'Honneur*. The Académie de Médecine, as might have been expected, is well represented in the rank and file of the Legionaries. It counts one Grand Cross (M. Pasteur), three Grand Officers

(M. Berthelot, the renowned chemist, Baron Larrey and Dr Rochard, the sanitarian), sixteen Commanders, comprising amongst others Charcot, Brouardel, Sappey, Proust, Tarnier, Péan and Verneuil, forty four Officers, thirty-eight Chevaliers. Only four members of the Academy are undecorated, MM Bouchardat, Laborde, Lagneau and Prunier. Baron Larrey (son of Napoleon the First's great surgeon), who was the President in 1863, has lived to see twenty one of his successors in the chair disappear from this world. They are in order of succession: Grisolle, Malgaigne (whose widow died this week), Bouchardat, Tardieu, Ricord, Blache, Danonvilliers, Wurtz, Barth, Depaul, Devergie, Gosselin, Bouley, Baillarger, Richet, Roger, Legouest, Gavarrat, Trélat, Perrin and Moutard Martin. The surviving Presidents are Baron Larrey, MM Chatin (1876), Hardy (1883), Guérin (1884), Bergeron (1885), Sappey (1887), Hérard (1888), Tarnier (1891), Régnaud (1892) and Laboulbène, who holds office this year. The fathers of the Academy are Baron Larrey, elected in 1850, and M Chatin, sen (1853).

The Abuse of an Exclusive Milk Diet in Bright's Disease

In a thoughtful paper published in the current number of the *Médecine Moderne* MM. Lecorché and Talamon call attention to the dangers attending the limitation of subjects of Bright's disease to a long continued milk diet. Such a warning is, I am sure, not superfluous, for the routine condemnation of such patients to this monotonous regimen for long periods of time is much too common an occurrence. The idea is widely spread and implicitly believed in that so long as a patient has albumen in his urine so long should he be kept alive exclusively on milk. The above mentioned physicians point out the danger of inducing what they denominate *anémie lactée*, and they cite several cases in which a resumption of ordinary diet has brought about a marked improvement in the general health of such victims without necessarily causing the diminution or disappearance of the albumen. They reserve the exclusive milk diet for cases of acute nephritis, from whatever cause arising, and for the accidents apt to occur during the course of chronic Bright's disease (*poussées aiguës brightiques*), such as hæmaturia, uræmia &c. Even here an average of from a week to a fortnight's milk diet gives all the good one can reasonably expect, a gradual return to a normal mixed diet should then be begun. During the intervals between these acute attacks they condemn the exclusive use of milk. It certainly appears that persons suffering from Bright's disease can live for years while passing albumen. I cannot but think that the nitrogenous food should be permanently restricted. I am in the habit of recommending the liberal use of rice cooked in different ways, believing it to be highly nutritious without exacting any undue work from the damaged kidneys.

January, 1893

Obituary.

ALFRED BAKER, F.R.C.S. ENG., J.P.

AFTER having attained to the full span of life the subject of this notice passed away on the 13th inst., to the deep regret of his numerous friends and former patients. Mr Baker was born on Jan. 23rd, 1815, and until recently showed but comparatively few marks of advancing age. Indeed his health was generally so good that, save for some epigastric trouble, he was contemplating removal from Birmingham to the more genial climate of Torquay. The above mentioned trouble, however, continued to increase and a consultation between Sir Andrew Clark and Dr Wade resulted in the diagnosis of malignant disease. Alfred Baker was one of seven sons, several of whom attained some distinction, either local or general. One of them became mayor of Manchester and received the honour of knighthood, another was a well known Unitarian minister, and a third became celebrated as a teacher of the deaf and dumb. His sister was the mother of the present Archbishop of Canterbury. Alfred Baker was educated at King Edward's School, Birmingham, where his talents seemed to give promise of an artistic career. During his educational career he was early thrown into the company of Henshaw, Creswick, A.R.A., Thomas Baker and others who afterwards distinguished themselves in art. His family, however, preferred that he should follow the medical profession and in 1832 he was apprenticed

to Mr J. J. Ledsam, who was senior surgeon to the Eye Infirmary. He was also entered as a pupil of the Old School of Medicine in Snow Hill, which was the precursor of Queen's College. There he obtained silver medals in the classes of anatomy, surgery, materia medica and therapeutics, a rare feat of subjects which foreshadowed the comprehensive ability which made him one of the most accomplished practitioners whom Birmingham has ever known. Mr Baker's facility in the use of the pencil and brush led to his early introduction by Joseph Hodgson into the wards of the General Hospital for the purpose of making for him pathological drawings and sketches of diseased parts and deformities. In pursuit of a frequent fellow worker was his friend Sir Will. Bowman, who was apprenticed to the hospital and was also, as was Mr Hodgson himself, an artist of no mean skill. Mr Baker subsequently acted as one of Mr Hodgson's dressers. Mr Hodgson's removal from Birmingham to London where he became president of the Royal College of Surgeons made no alteration in the friendship which existed between Mr Baker and himself. In 1836, having completed his curriculum of study in Birmingham, Mr Baker entered as a pupil at St. Bartholomew's Hospital and attended the practical lectures of the hospital, the brilliant lectures on surgery by Sir Will. (then Mr.) Lawrence, and the anatomical demonstrations by King's College by Professor Partridge. In 1837 he obtained his diploma of M.R.C.S. and at once returned to Birmingham. Declining an offer of partnership with his old master Mr Ledsam, he went to Coventry and for twelve months associated with Mr John Bury, whose public appointments and private practice made him the leading surgeon in the town. A vacancy in the post of house surgeon to the Birmingham General Hospital having become vacant, he sent in testimonials to the managing committee and succeeded in securing the appointment. In the discharge of the duties of this post he was enabled to effect considerable improvement principally in regard to the pathological examinations and the statistical records of the hospital. In 1843 Mr Baker resigned the stipendiary office of house-surgeon, and on the resignation of Mr B. Vaux was successful in obtaining honorary surgeonry to the institution. Here his administrative faculties, not less than his operative skill, were put to full play. In 1846 Mr Baker met with a serious accident. In the course of his professional work he was thrown from his gig and sustained a fracture of the femur as well as of one of the bones of the forearm. This accident confined him to the house for four months. His recovery was very slow and the accident left its mark in a slight lameness of the knee on the same side. In 1850 he married the eldest daughter of Mr George Armitage, a well known manufacturing chemist. In the same year he was associated with Dr Bell Fletcher, Dr F. Elkington, Mr George Elkington, Dr Russell, Dr J. B. Hayes and others in the foundation of a new medical school, which was known as Sydenham College. There had for some time past been a considerable amount of misunderstanding between the authorities of the General Hospital and Queen's College, and the object of the new school was to provide more efficient teaching, to combine in a greater degree theoretical training with practical demonstration under the same teachers, and thus to increase the value of the hospital practice. After seventeen years of active and successful work Sydenham College was amalgamated with Queen's College. During the whole of its existence Mr Baker held the office of lecturer upon the principles and practice of surgery. In the double capacity of honorary surgeon to the General Hospital and lecturer on surgery to Sydenham College it was Mr Baker's duty to acquaint himself with and to utilise such advances in surgical practice as were from time to time brought forward, and in fulfilling this object he was compelled to undergo the only recorded unpleasant experience of his public professional life. He had performed a dangerous surgical operation, which, though never carried out before in the General Hospital, had been previously performed with success elsewhere. The patient's death resulted in a charge of malpractice being brought against him—a charge which, however, was eventually disproved to the full satisfaction of the governors of the hospital. This notice would not be complete without a reference to his work in connexion with the various professional appointments he held. But his warmest interest was centred in the Birmingham General Hospital, in the management of which he took a valuable part. It was due to his suggestion in the first instance that the Infirmary Suburban Hospital was subsequently

established. Of indisputable skill as a surgeon dexterous manipulation, of sound judgment and careful in arriving at conclusions, Mr Baker's advice was sought with confidence. On his resignation of the honorary surgeonship of the hospital, a post he had held for thirty-three years a testimonial was presented to him by the committee consisting of his portrait, painted by Mr Frank Holl, R.A. and valuable service of silver plate. Nor were the warm congratulations of the students wanting on the occasion of his appointment as consulting surgeon to the hospital, when an illuminated address was presented to him on their behalf expressive of their admiration of his professional skill both as teacher and operator. On Mr Baker's personal qualities it is not necessary to dilate. The occupancy of high and honoured positions for many years forms sufficient testimony to his personal worth as well as to the integrity with which he discharged his responsible duties as a citizen and as a member of the profession which he adorned. He leaves a widow, four daughters and three sons, one of whom at present is Dean of Christ Church, Oxford.

WILLIAM LIDDON M.B. LOND. F.R.C.S. ENG.

We regret to record the death last week of Mr William Liddon of Taunton at the age of fifty-seven. Mr Liddon, after being educated in King's College School, entered the medical department of the College in October, 1853, and was one of its most distinguished students. He held the offices of assistant demonstrator of anatomy, physician accoucheur's assistant, and house surgeon; he became a Member of the Royal College of Surgeons in 1856, M.B. Lond. in 1858 and F.R.C.S. by examination in 1861, he obtained honours in anatomy and physiology at his first M.D. examination and in surgery at the final examination. He settled in practice at Taunton—the home of the Liddon family—was appointed surgeon to the Taunton and Somerset Hospital, and soon acquired a large reputation for his knowledge of surgery and his extensive experience, which were aided by a most courteous and kindly manner. In 1883 he was elected an hon. Fellow of King's College and always took a deep interest in King's College and King's College Hospital. He was a cousin of Dr Edward Liddon of Taunton and of Canon Liddon.

JAMES JOSEPH BUIST, M.D. ABERD., I.R.C.S. EDIN.

DR. BUIST, who died at his residence at Cardiff on Jan. 12th, was born in Banffshire in 1826 and had been a practitioner at Cardiff for the past thirty years. The deceased gentleman had for some time been suffering from heart disease, but the immediate cause of death was the rupture of a bloodvessel. He was a descendant of a very old Scottish Roman Catholic family and took his degree of M.D. at Aberdeen University in 1850 taking his L.R.C.S. at Edinburgh in the same year. In 1862 he was appointed house surgeon to the Glamorganshire and Monmouthshire Infirmary, which position he held for three years. He also held the position of honorary surgeon to the hospital ship *Hamadryad*. Dr Buist took a very great interest in the welfare of the poor and his death will be deeply deplored by many charitable institutions, to which he always was ready to lend a helping hand.

JOHN MCCAMBRIDGE, M.D. R.U.I. M.Ch.

DR. JOHN MCCAMBRIDGE of Widnes, Lancashire, died on Saturday Jan. 10th. He was a native of Randalstown, Antrim, Ireland, and took his degree of M.D. as well as that of M.Ch., at the Royal University in 1882. For the past ten years the deceased has practised in Widnes, and his death has caused much regret in that town. His remains have been removed to his native town in Ireland.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—An interesting conference of medical officers of health was held last week at Derby at which Dr Alfred Hill presided. The chief business was the inauguration in Derby of a new branch of the parent society. Dr Hill spoke of the success which had attended the co-operation of medical officers of health and stated that when he joined the Society seventeen years ago there were not more than 100 members connected with it, whereas the number now amounted to more than 600.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen have passed the Second Examination of the Board in Anatomy and Physiology at a meeting of the Examiners on the 12th inst. —

Arthur C. Friend of St. Thomas's Hospital, Arthur T. White and Arthur G. Littlehales of Westminster Hospital, Robert H. Mornement of Middlesex Hospital, Charles R. Matland of St. Bartholomew's Hospital, and Mr Cooke's School of Anatomy and Physiology, Bertie B. Ham, of the University of Melbourne, and Edward H. J. Danaher of London Hospital.
Anatomy only. Cornelius B. Garman and Edgar T. Lanyon of London Hospital, Percy A. Chilloct, of London Hospital, and Mr Cooke's School of Anatomy and Physiology, Sydney J. Haylock, of St. Mary's Hospital, Olaf F. Pritchard, of King's College, Stewart E. Douglas and Daniel L. E. Bolton of St. Bartholomew's Hospital, Charles F. Washill of University College, Samuel R. Hallam, of St. Thomas's Hospital, and Eugene Moore of Guy's Hospital.

Physiology only.—Richard Armitage of St. Bartholomew's Hospital, Harry F. Hyde, of Cambridge University and St. Bartholomew's Hospital, Ernest T. Clayton of Charing-cross Hospital, Arthur Scott-Turner, Berthon F. Pendred, Morton K. Crosslader, Leonard G. Reynolds, Archibald A. Price, and William G. Mitchell, of Guy's Hospital, Frank R. Proctor-Sims, of Guy's Hospital, and Mr Cooke's School of Anatomy and Physiology, Charles E. Walker and Robert C. Martin, of St. George's Hospital, Mohamed Abdul Ghani of Lahore Medical College and University College, Alfred J. Grant of St. Thomas's Hospital, John N. Macdonald, of St. Mary's Hospital, and Henry P. Cox, of King's College. Five candidates were referred in both subjects, five in Anatomy only and five in Physiology only.

UNIVERSITY OF CAMBRIDGE.—Mr Louis Cobbett, M.A. M.B. of Trinity College, has been appointed Demonstrator in Pathology in place of Dr Lloyd Jones, resigned.

MEDICAL MAGISTRATE.—Mr Robert McNICOLL, M.R.C.S., of St. Helens, Lancashire, has been placed on the Commission of the Peace for that borough.

FOOTBALL CASUALTY.—On Saturday last, during a match at Barnsley between the Barnsley St. Peter's and Mexborough teams, the captain of the latter team fractured his clavicle.

SANITARY AND BURIAL REFORM.—Dr B. W. Richardson presided recently at the monthly meeting of the Church of England Sanitary Association at the Church House. Mr Fred Scott, Secretary of the Manchester Sanitary Association, read a paper upon the Church, the Great National Sanitary Agency, Dr G. V. Poore, honorary secretary of the International Congress of Hygiene, read a paper upon 'Earth-to-earth Burial,' in which he maintained that burial in the earth could be rendered harmless to the living. A discussion followed, in which Sir Spencer Wells, Bart., Mr Morton, M.P., Canon Wilberforce and others took part. At the Funeral Reform meeting which followed resolutions were carried deprecating undue exposure of mourners at the grave and urging upon cemetery authorities the duty of keeping the cemetery chapels properly heated. Next day the Home Secretary received a deputation from the Church of England Sanitary Association and the Church of England Burial Reform Association, which was instructed to ask for *inter alia* the appointment of a Minister of Health, an exhaustive inquiry into the effect of earth to earth burial upon the subsoil, water, &c. and the more careful certification of the fact and cause of death in every case. The deputation which was introduced by the Duke of Westminster included the Bishop of Bedford, Sir Spencer Wells, Bart., Sir Henry Thompson, Sir Henry Roscoe, Sir G. Hunter, M.P., General Lowry, the Archbishop of London, Canon Scott Holland, Rev. J. W. Hocking, Rev. R. B. Ransford, Rev. T. B. Paynter, Dr G. V. Poore, Dr Norman Kerr, Dr Septimus Gibbon, Dr W. Squire, Mr Seymour Haden, Mr Braxton Hicks, Mr Smith Wright, M.P., Mr G. R. Benson, M.P., Mr Morton, M.P., Mr Earle and others. Mr Asquith, in reply, promised to communicate the views of the deputation respecting a Minister of Health to the Government, but could not encourage any hope of this part of the memorials receiving a favourable response. He said that the demand for an inquiry into the modes of the disposal of the dead had been clearly made out and he would consult with his colleague the President of the Local Government Board with a view to securing the more careful registration of the fact and cause of death in every case.

PENALTY FOR CONCEALING MEASLES—A case was brought before the Leith magistrates last week in which a lodging house keeper was charged with neglecting to give notice to the medical officer of health for the burgh of the existence of a case of measles in his house. It was proved that the defendant had been previously convicted of a similar offence, and the magistrates imposed a penalty of £2 and ordered that for three years the accused should be deprived of the liberty to keep or to aid in the care of a lodging house.

MUNIFICENT GIFTS TO HOSPITAL CHARITIES—Baron Hirsch, who recently gave £700 each to the North Eastern Hospital for Children and to the Royal Hospital for Children and Women, Waterloo-bridge-road, has forwarded to the Hospital for Sick Children, Great Ormond street, the sum of £1200 towards the payment of the debt incurred by the building of the just completed new wing. To King's College Hospital, to the Royal Free Hospital, Gryn's inn road, and to the Great Northern Hospital, Holloway road, he has given £700 each, to the Paddington Green Children's Hospital £300, and £200 have been received from him by the Royal Sea bathing Infirmary for Scrofula. The Southampton Dispensary has received from Mr Andrew Barlow the gift of £1000. The same gentleman recently gave a similar sum to the Royal South Hants Infirmary. The Dunoon Convalescent Homes have been presented by Mrs Galbraith of Glasgow with the sum of £500 for the endowment of a bed in memory of her late husband. This will enable seventeen persons annually to stay three weeks each in the home.

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number

- ANGUS, HENRY BRUNTON M.B. B.S. Durh. M.R.C.S. L.R.C.P. Lond. has been appointed House Surgeon at Southport Infirmary.
- BENNETT C. J., M.R.C.S., has been appointed Consulting Surgeon to the Cheltenham General Hospital.
- BURTON FANNING F. W., M.B. Camb. M.R.C.P. Lond. M.R.C.S., has been appointed Pathologist and Curator of the Museum the Norfolk and Norwich Hospital.
- CALCOTT G. W. B. M.R.C.S., has been appointed Medical Officer for the Oundle Urban Sanitary District of the Oundle Union, vice L. B. Calcott, resigned.

Medical Diary for the ensuing Week.

Monday, January 23

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., Fridays and Saturdays, at the same hour
 ST BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M. and on Tuesday, Wednesday, Friday, and Saturday at the same hour
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour
 CHELSEA HOSPITAL FOR WOMEN.—Operations 2 P.M., Thursday, 2 P.M.
 HOSPITAL FOR WOMEN, SOHO SQUARE.—Operations, 2 P.M., and on Thursday at the same hour
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
 ROYAL ORTHOPÆDIC HOSPITAL.—Operations 2 P.M.
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M., Thursday, 9 A.M. Eye Department, 2 P.M.
 LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital 1 P.M., Mr W Lang Lacrymal Affections.—101, Gt Russell st. 8 P.M., Dr Galloway Morbid Conditions of the Heart.—Parkes Museum (Margaret-st. W.) 3.30 P.M. Dr Parkes Disposal of Refuse.
 MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr J S Bristowe Syphilitic Affections of the Nervous System (Second Lettsomian Lecture)

Tuesday, January 24

GUY'S HOSPITAL.—Operations 1.30 P.M. and on Friday at the same hour
 Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
 ST THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., Friday, 2 P.M.
 ST MARK'S HOSPITAL.—Operations 2 P.M.
 CANCER HOSPITAL, BROMPTON.—Operations 2 P.M., Saturday, 2 P.M.
 WESTMINSTER HOSPITAL.—Operations 2 P.M.
 WEST LONDON HOSPITAL.—Operations 2.30 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Skin Department, 1.45, Saturday, 9.15
 ST MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays 1.30 P.M. Electrotherapeutics, same day, 2 P.M.
 ROYAL INSTITUTION.—3 P.M. Prof V Horsley The Brain.
 LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases Blackfriars 4 P.M., Mr Jonathan Hutchinson On Psoriasis.—Bethlem Hospital 2 P.M. Dr H. Corner Hysterical Mania, Religious Mania. 101, Gt Russell street 8 P.M., Dr Amand Routh Ovarian Tumours.
 ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Mr D Arcey Pwne Cases to illustrate the Relationship which exists between Wryneck and Congenital Hematoma of the Sterno Mastoid Muscle.—Mr Walter Rivington Some cases of Fracture of Long Bones from slight causes in connexion with Tabes Dorsalis Syphilis and Paraplegia

Wednesday, January 25

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M., Saturdays, 2 P.M. Obstetrical Operations Thursdays, 2 P.M.
 CHARING CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour
 ST THOMAS'S HOSPITAL.—Operations 1.30 P.M. Saturday same hour
 LONDON HOSPITAL.—Operations 2 P.M., Thursday and Saturday, same hour
 ST PETER'S HOSPITAL, COVENT-GARDEN.—Operations 2 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Operations 1.30 P.M. Dental Department, 9.30 A.M. Eye Department 2 P.M.
 ROYAL FREE HOSPITAL.—Operations 2 P.M. and on Saturday
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.
 LONDON POST-GRADUATE COURSE.—Hospital for Consumption Brompton 4 P.M., Dr J Mitchell Bruce Interesting cases of Phthisis in the Wards.—Royal London Ophthalmic Hospital 3 P.M., Mr A Stamford Morton Retinal Affections
 SOCIETY OF ARTS.—8 P.M. Mr Wyke Bayliss The Fine Arts in Relation to the Sanitary Condition of our Great Cities (Dr B W Richardson will preside)
 HUNTERIAN SOCIETY (London Institution).—8.30 P.M. Clinical Evening Dr A T Davies will exhibit a case of Tuberculosis of Palate, Larynx, and Lung and one of Hemilateral Diaphragms.—Dr Hingston Fox A case of Stenosis of Pulmonary Artery.—Dr W J Hadley (Introduced by Dr Arnold Chaplin) Two cases of Fibroid Disease of the lungs.—Mr F R Humphreys Notes of Two cases of Cheyne-Stokes Respiration with recovery.—Dr F C Turner Intestinal Obstruction

Thursday, January 26

ST GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday 1.30 P.M. Ophthalmic Operations, Friday 1.30 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Operations 2 P.M. Ear and Throat Department, 9 A.M. Eye Department, 2 P.M.
 LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond-street 4 P.M. Mr J H Morgan Tracheotomy.—National Hospital for the Paralyzed and Epileptic 2 P.M. Dr Beevor Cerebral Localisation.—London Throat Hospital (St. Portland-st.) 8 P.M. Dr E Law Examination of the Throat and Nose.—Central London Sick Asylum 5.30 P.M. Mr John Hopkins Cases in the Wards
 CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn road).—5 P.M. Dr Dundas Grant Acute Inflammation of the Middle Ear
 OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Patients and Card Specimens at 8 P.M. Mr W M Beaumont Congenital Ectopia Pupille.—Dr J Stephenson A Set of Strocchini's Drop Bottles.—Mr Haxbridge Refinitis in Leucocytæmia.—Mr Priestley Smith (1) Toxic Amblyopia from Iodoform, (2) A Double Model Eye for Ophthalmoscopy and the Shadow Test, (3) Improved Model Illustrating Conjugal Movements.—Mr R W Doyle Foreign Body in the Eye.—Dr J Hearn Simple Photophobia and its Treatment by the Constant Current.—Dr A. Sandford Enlargement of both Lacrymal Glands causing Closure of the Palpebral Apertures removal.—Mr J Tatlam Thompson Ledgment of a Fragment of Steel in the Vitreous unusual track.—Dr A Bronner A peculiar case of Membranous Conjunctivitis.—Dr Sydney Stephenson Concerning Persistent Pupillary Membrane and its frequency

Friday, January 27

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Eye Department, 2 P.M.
 LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton 4 P.M., Dr Percy Kidd Tubercular Affections of the Throat.—Bacteriological Laboratory King's College, 11 A.M. to 1 P.M., Prof Crookshank Cultivation of Bacteria (Cultivations).
 LONDON SKIN HOSPITAL (40 Fitzroy sq., W.)—3 P.M. Dr Saxenay Eczema, its Treatment in connexion with other Diseases and General Review
 CLINICAL SOCIETY OF LONDON.—Living Specimens at 8 P.M.—Mr C Mansell Moullin A case of Superficial Resection of the Superior Maxilla.—Mr Malcolm Morris A case of Urticaria Pigmentosa.—Dr Samuel West A case of Dermatitis Herpetiformis.—Dr Arlin Davies Cases of Myxedema treated by an improved method of giving the Thyroid Extract.—Dr Hector Mackenzie (1) A case of Myxedema of over four years' standing cured by Thyroid Feeding (2) A case of Myxedema treated with benefit by means of a Powder prepared from Thyroid Glands.—Dr Pasteur A case of Myxedema treated by Thyroid Gland Extract.—Mr Watson Cheyne A case of Nervoid condition of Limbs, with Enlargement and Elongation of Bones Papers at 9 P.M.—Mr Arbuthnot Lane A case illustrating a more effectual method of Removing a Cancerous Breast, Lymphatic Glands.—Mr R W Parker On the relative Merits of a Vertical and of a Transverse Incision in Supra pubic Cystotomy (with case Mr Arthur E Barker Subserous Uterine Hematocoele in a Girl eleven years simulating acute Appendicitis, Laparotomy, Recovery Mr F Eve A case of Unusual Form of Tuberculosis of Arm. Mr B Watne Wright A case of Exclusion of several Synovial Membranes for Tubercular Disease

Saturday, January 28

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and Skin Department 9.15 A.M.
 LONDON POST-GRADUATE COURSE.—Bethlem Hospital 11 A.M., Dr Percy Smith Mania

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to a gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention given to this notice

It is especially requested that early intelligence of local cases having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to the Office

Lectures, original articles, and reports should be written on one side only of the paper

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor"

Letters relating to the publication, sale and advertising particulars of THE LANCET should be addressed "To the Publisher"

We cannot undertake to return MSS. not used

PUBLISHER'S NOTICE

IN order to facilitate the work of reference to the volume of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET

"THE LANCET" LABORATORY

Dr M A Boyd.—We do not undertake to conduct private analyses. The work of THE LANCET Laboratory is carried out entirely at the proprietors' expense and is devoted wholly to matters relating to public health and the analysis of drugs and articles of food so far as they are considered to be of interest and concern to the medical reader

Dr J G.—The M.D. of Brussels is not registrable in England or as far as we know, in Victoria. The M.D. degree of Melbourne cannot be obtained *ad eundem* by a graduate of Brussels

DREAD OF CONTACT

MRS. LANNOLIS and WEILL recently brought before the Lyons Medical Society the case of a man who suffered from a peculiar mental state which makes him dread the touch of another person. He moves away if anyone comes near him and withdraws his hand if anyone attempts to take it, he is in a continual state of restlessness and if any person is behind him keeps turning his head for fear he may be touched. In hospital, if anyone approaches for the purpose of examining him, he jumps out of bed. Once he jumped from a first floor because some one came near him. He was brought into hospital because he was seized with an attack of some kind in the street, and was found to be suffering from aphasia. His fear of contact, which Drs. Lannolis and Weill designate "aphephobia," seems to be hereditary, his brother and a nephew suffering from the same affection.

FEES FOR MEDICAL EVIDENCE.

To the Editors of THE LANCET.

SIRS.—Will you kindly advise me as to whether I am entitled to a fee in the following case?

I had under my care in the hospital to which I am attached a patient suffering from a burn after being detained for several weeks she was transferred to an infirmary, where three weeks later she died. I was summoned to give evidence at the inquest but, having unfortunately lost the form I am unable to say if it was an ordinary or medical subpoena. At the inquest my evidence was taken as to the condition of the patient on admission, her condition while under observation and her state on discharge, with the reasons for her transference. My request for the usual fee was refused. In a subsequent letter the coroner based his refusal on the following grounds—"1. That you were not summoned as a medical witness by the usual medical summons. 2. That your evidence as a professional man was not required. 3. That you had relieved yourself from your responsibility as a medical man by discharging the deceased from your hospital and sending her to the infirmary. 4. That the reason you were summoned was to explain the fact of such removal." Surely the evidence I was called upon to give was of a purely professional nature and as such entitled me to a fee. Apologising for troubling you

I am, Sirs, yours truly

Jan. 17th, 1893.

HOUSE SURGEON

"It is difficult and sometimes impossible to define what is simply fact and what scientific opinion. Even if our correspondent were called as an ordinary witness it must have been difficult to have limited his examination to non professional matters. The first reason, if correct, and our correspondent is not in a position to deny it, given by the coroner would bar him from having a legal claim to a fee. With the third reason we do not agree. The discharge of the patient relieved our correspondent from responsibility as a practitioner but not as a medical witness.—ED L.

THE NURSING OF PARALYSED PATIENTS

In the columns of THE LANCET of Jan 7th, p 69 "M B" inquired as to the best material to use in the case of a patient in poor circumstances suffering from incontinence of urine and paralysis and unable to wear a urinal. A correspondent, writing from experience in a recent case which was found very difficult to manage—the case of a lady suffering from paralysis, incontinence of urine and faeces and bed sores—recommends the use of tow made into pads of twenty inches square with unbleached muslin. These are to be placed on water proof sheeting.

HOSPITAL DRESSERS TABLE.

To the Editors of THE LANCET

SIRS.—Under the heading of "New Inventions" in THE LANCET of the 7th inst appears a notice with woodcut of the above table. In THE LANCET of Sept 12th, 1891, page 616 you were good enough to notice a new surgical dressing waggon, invented and patented by Mr Bigg of Oxford. Now the table described in THE LANCET of this week is the exact counterpart of the one invented by Mr Bigg. These tables are made with marble glass or enamelled top with or without glass or porcelain trays, the drawers run the entire length of the table and can be opened from either side and there is a shelf for bowls &c. It is provided likewise with towel rail at the back and mounted on castors. Upon comparison you will find the table introduced by Messrs Carter is a facsimile of the one invented and patented by Mr Bigg, and of which we are the sole agents. We remain Sirs, yours faithfully

West Smithfield, Jan. 11th 1893.

ARNOLD & SONS

MEDICAL ADVERTISING

THE following extract from the advertising columns of the *Evening Advertiser* is another illustration of an insidious and growing evil. We acknowledge that it draws the line at a more modest point than in some other cases. But it violates the rule that medical men are not to seek practice and publicity through the advertising columns of newspapers—

Card—Dr David Donald begs to intimate that he has commenced the practice of his profession in Buchhaven.—Rowan Cottage West Wynd Buchhaven."

'THE SOURCES OF OUR ICE SUPPLY'

In an article in a recent issue of THE LANCET we drew the attention of our readers to the possible pollution of the sources of our natural ice supply. Mr T B Lightfoot, M.L.C.E. writes to say that there can be no doubt that in some instances disease has actually been traced to the use of contaminated ice. Such cases he affirms are well authenticated. There is however, in many large towns no difficulty, he points out, in procuring ice that is free from such objection. In London, Birmingham, Hull and elsewhere large quantities of ice are made from water that has actually been distilled while still larger quantities are artificially produced from drinking water. There are, in fact, few large towns unprovided with ice-making factories. He mentions as an instance large ice works in the East of London which produce about 120 tons per day one-half from distilled and one-half from main water. Refrigerating machinery, he adds, is now almost universally used for the storage of meat fruit, dairy produce and other perishable commodities and the present tendency is for such machinery to replace the use of ice even in small stores for butchers, game dealers &c. The temperature can be more easily regulated than with ice and the air is dried and purified, matters which are, of course, of paramount importance in the proper preservation of foods. The cost is also said to be less.

'VARICOSE VEINS AT THE ROOT OF THE TONGUE'

To the Editors of THE LANCET

SIRS.—In THE LANCET of Jan. 7th your correspondent, 'Ignoramus' asks for information with regard to varicose veins at the root of the tongue. I believe I was the first to draw attention to this subject in a paper at the International Medical Congress at Milan in 1890 and again by invitation, before the Philadelphia Medical Society in 1897. In these communications I endeavoured to point out that the varicosity in this situation was one of other objective reasons for many of the subjective symptoms generally considered as "hysterical" and also for many cases of hemorrhage of the throat which had sometimes led to a mistaken diagnosis of pulmonary disease. At the Birmingham meeting of the British Medical Association in 1890 I read a paper on Pharyngeal Tenesmus pointing out that these subjective symptoms in the throat were very analogous to similar sensations in the rectum and were caused by varicosity and an overgrowth of the adenoid tissue constituting together what I ventured to designate as "lingual hemorrhoids" or "throat piles."

I am Sirs, yours faithfully

Manfield street, W Jan. 9th 1893

LEYNOR BROWNE.

DEATH OF A FRENCH MEDICAL STUDENT

M. GÉRARD, a student of the French School of Military Medicine has recently died of an attack of diphtheria contracted in the course of some researches he was making on the ear of the fetus.

ERRATA.—In our account of the meeting of the Forfarshire Medical Association in our issue of last week, page 88, at lines 6, 7, 20 and 40, 'urea' should have been 'ria' at line 27 'sulphuric' ought to have been 'sulphonic' at line 41 'Lieber' should have read 'Sieber'.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

The Hunterian Oration,

Delivered in the presence of their Royal Highnesses the Prince of Wales and the Duke of York at the Royal College of Surgeons of England on the Centenary of Hunter's Death, Feb 14th, 1893

By THOMAS BRYANT, F.R.C.S. Eng. & I., M.Ch.
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND
CONSULTING SURGEON TO GUY'S HOSPITAL.

PART I.

HUNTER AS A THINKER AND REASONER.

MAY IT PLEASE YOUR ROYAL HIGHNESSES MR. VICE PRESIDENT, MY LORDS AND GENTLEMEN,—I feel sure that I am but expressing the general sentiment of the representative body of surgeons here assembled when, in their names and in that of the College over which it is my privilege to preside, I offer to your Royal Highnesses our respectful thanks for your presence here to-day. We venture to accept your presence on such an occasion at the celebration of the centenary of the death of the great founder of scientific surgery as an indication of your approval of the work of this College as a public institution, and as a promoter of the scientific surgery that John Hunter established. We would assure your Royal Highnesses that your visit will not only be gratefully remembered but prove to be a powerful incentive to our continued good work as the national custodians of the Hunterian Museum, guardians of Hunter's reputation and promoters of the art and science of surgery.

One hundred and sixty five years ago a careful observer might have read in one of the papers of the period the announcement that on Feb. 14th, 1728, the wife of John Hunter of Long Calderwood, in the parish of East Kilbride, East Lanarkshire, about eight miles from Glasgow gave birth to a son, this son being her tenth child, her husband being then sixty four years of age. Sixty-five years later—that is, in 1793, or one hundred years ago—another observer would have read in the *Oracle* of Oct. 18th an intimation of the death of this son, who had been named John after his father, in the following terms: "This eminent surgeon and valuable man was suddenly taken ill on Wednesday (Oct. 16th) in the council room of St. George's Hospital. After receiving the assistance which could be afforded by two physicians and a surgeon he was removed in a Sedan chair to his own house in Leicester square, where he expired about two o'clock, in his sixty sixth year. The profession has lost in him one of its principal pillars and brightest ornaments and mankind may lament in him one of their best benefactors. The ardour and success with which he cultivated natural knowledge and philosophy and rendered them subservient to his profession had deservedly raised him to the first name. The monument of industry and genius which he has left behind will best speak his praise and call for the gratitude of this and future ages."

These two announcements intimated to the world the beginning and ending of the life of a man who has become one of the most brilliant of the fixed stars of our national genius, and he became so, not so much by his contributions to the stock of human knowledge, which in themselves were colossal, as by his opening up a line of investigation which was entirely original, and by his marking out in the clearest way the paths which all future investigators must tread who desire to decipher the problems of life, disease and death. During this century "Great men have been among us hands that penned and tongues that uttered wisdom," but to-day we celebrate the death of the greatest, and I would that I had the wisdom of a Bacon and the eloquence of a Burke to do justice to his memory. As a humble disciple, however, of John Hunter and in the presence of his followers, many of whom have in adding lustre to his reputation acquired much for their own, I propose to display before you some of the leading conclusions of his life, and by trying to understand his methods and modes of work learn how we can help ourselves and those who may follow us to maintain, extend, and develop what will endure for all time—the school which Hunter originated and to which every good surgeon since his age has unquestionably belonged, for the Hunterian era of surgery which is rightly marked by Dr. Billings of Washington as the starting point of modern surgery, is now established

and it is but right that we, its professors, should do our best, not only to encourage the study of Hunter's works, which have a power of awakening thought and stimulating industry of a unique character, but to provoke those who shall come after us to the imitation of whatever there was of good report, noble, or lovely in Hunter's life, as well as in the lives of those who since our last oration have, in the words of Dante,

"Doffed this garb of frail mortality"

I would here introduce the names of some distinguished Fellows of our College, with the dates of their death, who have gone "where we all must go" since our last oration. Sir Prescott Hewett died, aged seventy nine, on June 19th, 1891, John Wood, aged sixty six, on Dec. 19th, 1891, Berkeley Hill, aged fifty eight, on Jan. 7th, 1892, Sir William Bowman, aged seventy six, on March 29th, 1892, Charles Hawkins, aged eighty on April 4th, 1892, F. Le Gros Clark, aged eighty-two, on July 19th, 1892, Edward Cock, aged eighty-seven, on Aug. 1st, 1892, Samuel A. Lane aged ninety, on Aug. 2nd, 1892, Alfred Baker, aged seventy eight, on Jan. 12th, 1893—all good Hunterian surgeons who made for themselves names which will long be remembered by the members of the profession they adorned, and many of whom held high office in this College, and last, but not least, I must mention the name of our oldest Fellow, that great anatomist, biologist and natural historian, Hunter's greatest expositor, Sir Richard Owen, who died on Dec. 18th aged eighty seven, and by his long and well-spent life not only left natural science greatly his debtor, but by his genius and industry attracted to the museum of this College the attention both of the scientific and lay world and helped, in a measure which is difficult to calculate, during the twenty-eight years of labour he devoted to our Hunterian collection as Clift's assistant, and our conservator and professor to place it in the proud position in which it now stands. May this College never forget these signal services, nor fail to do honour to the memory of this great man.

I have no intention of entering into the particulars of Hunter's early life, but, brought up as he was by a loving mother and guided by a father 'who maintained to the very end of his life (1742)—that is to his son John's fourteenth year—a clear and sound judgment, as well as the tenderest and wisest interest in the welfare of his children' (Simmon's letter) there is no reason to think that John, more than any of his children was left uncared for, but every reason to believe it probable, with Luther Holden, our eloquent orator for 1881, that John was educated at the same school as his brothers William and James, and that he was brought under the influence of an equally good moral training. That he spent much of his time in country amusements and country pursuits is more than probable, but that he did so as an idler is beyond belief for on his own authority we have it stated that when "I was a boy I wanted to know about the clouds and the grasses and why the leaves changed colour in the autumn, I watched the ants, bees, birds, tadpoles and caddis worms. I pestered people with questions about what nobody knew or cared anything about," and can we, with our full knowledge of the man and of what he subsequently achieved, say that the education he has himself described so tersely and so well was not for him the very best he could have had? For, 'as the child is father of the man,' is it not as clear as daylight that all his senses had been educated to the highest degree, and that not one had been allowed to slumber, whilst his reasoning powers had been brought to bear upon problems of the highest interest concerning things above, upon and beneath the earth, and in what better way could they have been employed? It was not, however till he came to London at the age of twenty that his "natural fitness for the study of living things" had full scope in the dissecting room and museum of his highly distinguished brother William. For it was there that new worlds of wonder were opened to him in human and comparative anatomy, and it was there likewise that he used his opportunities of questioning nature so well, as not only to open up fresh avenues of knowledge, but to demonstrate the necessity of making comparative anatomy and physiology preliminary studies to that of life as well as of disease, pathology following in the line of physiology. Hunter's physiology, moreover was of no narrow type, but of the broadest and deepest character. Indeed, it included 'the whole science of the normal life of all things that live or have lived in both the vegetable and animal kingdoms, and his comparative anatomy was no less inclusive, for it took in the comparative structure of all living things with

the uses and functions of their different parts. Whilst he unveiled many of the secret operations of nature, his material was so arranged as to illustrate the workings of every vital process as displayed in each organ, and traced through every gradation of being, from the lowest to the highest, or, to quote from our second conservator, the late Sir Richard Owen, "his labours not only established a body of physiological doctrines, to the happy influence of which every cultivator of the healing science now bears grateful testimony, but they deserve to be viewed in the light of a first attempt to arrange in one concatenated system the diversified facts in comparative anatomy", comparative anatomy in Hunter's time being a new science.

If we ask ourselves what it was which helped to make Hunter great, we must, as an encouragement to weak humanity, refer to his industry, for John Hunter was industrious in the highest degree and possessed a transcendent capacity for taking trouble. Without this attribute it is probable that his other great qualities would have failed to have made him famous, and they certainly would never have enabled him to leave the unique collection of biological facts behind him, such as is contained in the museum it is our pride as Englishmen and our privilege as British surgeons to possess. I emphasise this quality of industry, as it can never be too strongly or frequently repeated that industry and the capacity of taking trouble are essential qualities for success in every calling or walk in life, and that without them all intellectual qualities, however noble, are apt to be frittered away and rendered futile. The pages of history record the wreck of many men of high promise and intellectual ability who have failed to shed a lustre upon their period for want of this essential qualification. As an additional testimony to Hunter's industry let me quote from a lecture of our late curator—a successor of Sir Richard Owen—now so worthily known as Sir Wm. Flower, in which he said "that Hunter had collected materials for a work which needed but the finishing touches to have made it one of the greatest, most durable, and valuable contributions ever made by one man to the advancement of the science of comparative anatomy".¹ So that on the authority of the late Sir Richard Owen we have it stated that Hunter made the first attempt to establish a new science, that of comparative anatomy, and on the authority of Sir Wm. Flower we are told that the success of the attempt was in itself complete. As an observer John Hunter stands pre-eminent, and as an indefatigable student of nature he was supreme, nothing escaped his attention, and what he observed he verified so carefully and thought over so intently that he saw more accurately, deeply, widely and sagaciously than anyone else. In all his works Hunter followed the Baconian method, and yet we have no evidence that he knew anything of Bacon's work or of the inductive mode of reasoning which he introduced. Hunter, apparently out of the depth of his own nature, unconsciously travelled along the Baconian road. From boyhood, as he himself has told us, he had observed and interrogated nature in many of her works, and as a result of his observations high problems had been suggested. He wanted even then to know many things which seem still unknownable. This want indeed never left him and to supply it he, as life went on, diligently sought for every fact his senses could discover in the different lines of investigation he followed, and, what is more, described the facts he found with an accuracy which is absolute, where he was uncertain of his facts he looked again, and to test a doubtful one he experimented. He always doubted what he could not prove. Hunter observed to find facts, and experimented to make and to prove them. The absolute necessity of *accuracy of observation* was so fully recognised by Hunter that he trusted nothing to memory, but wrote down what he saw at once, for, using his own words he felt that "men should be very accurate in ascertaining the truth of facts before they advance them, especially when they tend to overturn a received opinion or to establish a new one".

If Hunter was great from his industry and as an observer, he was still greater as a *thinker and reasoner*. Facts alone could not satisfy his mind. He, of necessity, speculated upon their value, and reasoned upon them with a closeness and far seeing intelligence which was surprising. He seemed as by intuition to recognise at once the full value of any fact and to be able to place it in its right position in relation to all knowledge, as a consequence, he was able, from the accumulation of the material which his observation and

experience had yielded, to elicit the principles upon which they were founded and the processes by which they were brought about. Much as Hunter did, said his friend Cline in this theatre in 1816, "he thought more. He has often told me his delight was to think." "The facility with which a man thinks," said Hunter himself, "gives him a superiority over others, few," he added, "have observed nature with more attention than myself, yet, even now, I think myself scarcely equal to the task I am undertaking—the elucidation of the economy of human life." Again, in the year 1768, "I," wrote Hunter, "was called upon to be a teacher of anatomy, but I congratulate myself that I did not become so, as it could not have failed of engaging my attention too much to admit that general attention I have been able to pay to surgery, and the necessity I should have been under to read might have occupied me too much and prevented my forming habits of established modes of thinking." Again, "what, more than all, induced me to lecture was the great advantage everyone finds by putting his thoughts into writing. A man can never tell how much he knows till he arranges his knowledge, and then he can tell how defective it is." It must therefore be accepted that deep thinking was one of Hunter's characteristics, and I can give you no better evidence of this than that quoted by Abernethy, on the authority of Clift, "that Hunter would stand for hours motionless as a statue, except that with a pair of forceps in either hand he was picking asunder the connecting fibres of some structure he was studying," and this was written of him in the year of his death.

What a picture is here presented to our minds of Hunter as an inductive thinker! The new fact displayed to view after infinite trouble. The dissector patiently reasoning out its meaning standing for hours, in the words of an eloquent friend, before me, "patient and watchful as a prophet, as if he were sure that the truth would come—in the clearing of some mental cloud, or as in a sudden flash, with which, as in an inspiration, the intellectual darkness became light."² The picture is complete. It should be painted by another Reynolds. But Hunter was more than a thinker and reasoner on facts, although as a man of science he contemplated nature with his understanding, and, as a lover of truth, he kept to his facts, for he possessed to an equally high degree imagination and an intellectual foresight, with that higher degree of intellectual power which enables a man to recognise a truth directly it is enunciated, to perceive self evident facts, and through them to read the laws and fundamental principles by which nature works. He obtained his ideas as much through the reason by reflection as through the senses. In the speaking portrait above me this mental characteristic of John Hunter is displayed in a manner which genius alone could have depicted, for the thinker is clearly looking upwards as if he had heard "whisperings from the Infinite," and at the moment when one of the laws by which nature works had suddenly dawned upon him. He is manifestly looking beyond the mists which surrounded the wonderful world of life he had so long been investigating and many of the mysteries of which it had been his privilege to unveil. Indeed, Hunter's intellectual faculties had been so highly educated and were of so high an order that he was able to read the unknown truth in the known fact and by observation and thought to work out principles and general truths which have thrown a flood of light for ever not only upon all past but upon future knowledge. And what is more, his work has been so suggestive that whilst we his successors, adopt his thoughts we profit by the thoughts that his suggest. In all Hunter's work fact and theory were indissolubly bound together, and as a proof that his theories were good every fresh fact he discovered found its place in them. "My mind is like a beehive," said Hunter to Abernethy, one of Hunter's friends and earliest and most enthusiastic expositors, and "the simile struck me," wrote Abernethy, "on account of its correctness for in the midst of buzz and apparent confusion there was great order, regularity of structure and abundant food, collected with incessant industry from the choicest stores of knowledge." Hunter apparently had no idea of his own great intellectual powers. Abernethy records he had heard Hunter say, "I know I am but a pigmy in knowledge," and declare that he was not conscious of possessing any peculiar talent, and that if he had promoted professional knowledge it seemed to him chiefly to have arisen from his disposition to distrust opinions and to examine every subject

¹ Introductory Lecture, Royal College of Surgeons, Feb. 14th 1870

² Sir James Paget Hunterian Oration, 1877

for himself. But it may be fairly asked, Was not this state of Hunter's mind due to the fact that his knowledge was so great that he knew his littleness? I rather incline to this latter view.

Hunter was a nervous man and much disliked speaking in public. He never gave his first lecture, wrote Sir F. Home, without taking thirty drops of laudanum to take off the effects of his nervousness. Hunter lectured always from notes which he read, and from comparing different copies of his lectures I am sure that he divided his subjects into aphoristical paragraphs, which he subsequently enlarged upon and illustrated by cases. He also revised and corrected his great work on the blood, inflammation, and gunshot wounds for twenty years before he prepared it for the press, and he then died before it was published. He did this because he was always unwilling, to publish anything which appeared to himself unfinished, for the same reason he would often withdraw papers read before the learned societies because he felt they wanted something more to make them satisfactory. With Hunter this cautiousness was something of a misfortune, for his great work on inflammation and gunshot wounds upon which so much of his professional reputation has been built, was not published till after his death, and had it not been for his public lectures in the school of St. George's Hospital and at 28 The Haymarket, his advanced views of pathology and surgery would during his lifetime have been little known. It was probably on this account that Hunter was insufficiently appreciated. His teaching was known but to a few. It is interesting to speculate as to what would have been the effect of this cautiousness in publishing if it had been as rigidly observed by Hunter's followers as it was by Hunter. Should we have been great losers by its adoption and would individuals have been great gainers? Could we now with any truth agree with Hunter when he wrote "That it is surprising to see how a young man, if he catches an idea which has any novelty will write away on it—he will tell you wonders," and can we say, if the tillers of the field of science are now more numerous than they were in Hunter's day that they are so eager to reap the fruit of their labour as to bring it to market before it is ripe? Extreme cautiousness and a dread lest he might have been led to publish any new thought before it was absolutely proved was evidently one of Hunter's characteristics, and, as a further proof of this it should be added that Hunter always regarded any opinion or conclusion he formed as provisional, for he felt that one new fact or observation might lead him to change it. He would say to students he was teaching "You had better not write down that observation, for very likely I shall think differently next year."

As an experimenter Hunter was a king and a model one. He never made an experiment without a definite object, either to illustrate an idea, prove a fact clear up a doubt or enable him to grasp a truth which he could not prove, and although he made every investigation that he could the subject of experiments each one was preceded by deep reflection. In one place he said "that it was not justifiable to draw conclusions from a single experiment." In another, "I think it may be set down as an axiom that experiments should not be often repeated which merely tend to establish a principle already known and admitted, but that the next step should be the application of that principle to useful purposes," and later on he wrote, "We can have no very high idea of experiments made by men who, for want of anatomical knowledge, have not been able to pursue their reasoning beyond the simple experiment itself. It happens, unfortunately," he added, "that those who from the nature of their education are best qualified to investigate the intricacies and improve their knowledge of the animal economy, are compelled to get their living by the practice of a profession which is constant employment." To his friend Jenner, who had given only a conjectural solution of the phenomenon, he wrote "I think your solution is just, but why think? Why not try the experiment! Repeat all the experiments as soon as you receive this and they will give you the answer. Fontana's experiments," he wrote, "for injecting solutions into the blood are not worth a pin, and that owing to his not having a knowledge of this fact—that air thrown into the vessels kills. After I discovered this I went over all my experiments again and found very different results when I injected no air, which before that had been frequently inserted."

Now I must give one further quotation from Hunter as to the general outcome of experiments. "In pursuing any subject most things come to light. It were by accident—that is,

many things arise out of investigation that were not at first conceived, and even misfortunes in experiments have brought things to our knowledge that were not, and probably could not have been, previously conceived. On the other hand, I have often devised experiments by the bedside or in my carriage, and have also conceived the result, but when I tried the experiment the result was different, or I found that the experiment could not be attended with all the circumstances that were suggested."

These views of Hunter upon experiments cannot be other wise than valuable. They are characterised by absolute honesty of purpose and breadth of knowledge. Last, but not least, Hunter *worked for fame and not for profit*. What he made in his profession he spent on his museum, and when he was interrupted in his scientific pursuits to earn a fee he went because he knew he would want the fee to-morrow to supply his needs. He never went from choice, for his inclination would have held him closely to his work. He was also an enthusiast in all he did, and he therefore worked with a will. And can we wonder at his being so? for at every step in his investigations fresh natural beauties were being revealed, and at every resting place with his luminous mind these fresh beauties suggested the laws and principles on which they rested. And, if in us the mere reading of his works produces an intellectual pleasure of a stimulating and awakening nature, with what an intense thrill of satisfaction must the first vivid conception of those secrets of the laws of nature have been attended in his frame, and with what natural reluctance would he have left his dissecting table!

I have thus, then, so far in this lecture been considering Hunter as a worker, for it has been my privilege and pleasure to place before you the main mental characteristics of an vigorous and original a human being as mankind has ever seen, of one who came into the world with little promise, and some say with less advantages than most, but whose faculties budded out so rapidly under favourable conditions as to enable their possessor to remodel the fabric of knowledge and revolutionise our modes of thought, as well as to bring forth leaves, flowers, and fruit for his own generation to wonder at, and for all future generations to enjoy and feed upon, for the flowers and fruit of Hunter's genius are everlasting. I might add that Hunter was said by Sir E. Home to have been of a short stature. By Dr. Adams he was described as being much below the middle stature. By Mr. Clift he was said to have been five feet two inches, and Clift must have been right. He was uncommonly strong and active, very compactly made, and capable of great bodily exertion. His countenance was animated, and in the latter part of his life deeply impressed with thoughtfulness, and thus we can well understand if we attempt to understand such a man at all and if the information we have of his thoughts and doings is correct.

In the sketch of Hunter's character and mental characteristics which I have ventured to place before you I have taken the liberty of illustrating Hunter by Hunter, for I felt that so remarkable a man could be best interpreted by himself, and I have thus quoted his own words where they could be found rather than the opinions of others, and his own acts as they have been recorded in his works. Indignantly, therefore, we must pronounce the verdict that John Hunter as a man had individual and intellectual qualities which have never been surpassed, if ever equalled, and if he had imperfections we will not look for them, for he was human, and no shortcomings could dim the lustre of his splendid genius.

PART II.

HUNTER AS A BIOLOGIST

I will now pass on to consider what Hunter did, and I fear that here failure must follow the attempt, for in re-reading all his works and the works of his commentators I feel almost lost in wonder at the magnitude and variety of his undertakings and of his performances, for the whole world of vegetable and animal life was his subject, and the workings of everything possessing life the objects of his scrutiny. If form and structure were his chief early studies, function and purpose always occupied a large part of his attention, and these he regarded as much in a state of health as under the influence of disease, as much in their abnormal as in their normal relations. "Vital operations were," he said, "always his favourite business and amusement." Yet this study of all these subjects was only a means to an end, and was subordinate to the main object of his life—namely, the improvement of surgery by the elucidation of pathology.

the uses and functions of their different parts. Whilst he unveiled many of the secret operations of nature, his material was so arranged as to illustrate the workings of every vital process as displayed in each organ, and traced through every gradation of being, from the lowest to the highest, or, to quote from our second conservator, the late Sir Richard Owen, "his labours not only established a body of physiological doctrines, to the happy influence of which every cultivator of the healing science now bears grateful testimony, but they deserve to be viewed in the light of a first attempt to arrange in one concatenated system the diversified facts in comparative anatomy", comparative anatomy in Hunter's time being a new science.

If we ask ourselves what it was which helped to make Hunter great, we must, as an encouragement to weak humanity, refer to his industry, for John Hunter was industrious in the highest degree and possessed a transcendent capacity for taking trouble. Without this attribute it is probable that his other great qualities would have failed to have made him famous, and they certainly would never have enabled him to leave the unique collection of biological facts behind him, such as is contained in the museum it is our pride as Englishmen and our privilege as British surgeons to possess. I emphasise this quality of industry, as it can never be too strongly or frequently repeated that industry and the capacity of taking trouble are essential qualities for success in every calling or walk in life, and that without them all intellectual qualities, however noble, are apt to be frittered away and rendered futile. The pages of history record the wreck of many men of high promise and intellectual ability who have failed to shed a lustre upon their period for want of this essential qualification. As an additional testimony to Hunter's industry let me quote from a lecture of our late curator—a successor of Sir Richard Owen—now so worthily known as Sir Wm. Flower, in which he said "that Hunter had collected materials for a work which needed but the finishing touches to have made it one of the greatest, most durable, and valuable contributions ever made by one man to the advancement of the science of comparative anatomy." So that on the authority of the late Sir Richard Owen we have it stated that Hunter made the first attempt to establish a new science, that of comparative anatomy, and on the authority of Sir Wm. Flower we are told that the success of the attempt was in itself complete. As an observer John Hunter stands pre-eminent, and as an indefatigable student of nature he was supreme, nothing escaped his attention, and what he observed he verified so carefully and thought over so intently that he saw more accurately, deeply, widely and sagaciously than anyone else. In all his works Hunter followed the Baconian method, and yet we have no evidence that he knew anything of Bacon's work or of the inductive mode of reasoning which he introduced. Hunter, apparently out of the depth of his own nature, unconsciously travelled along the Baconian road. From boyhood, as he himself has told us, he had observed and interrogated nature in many of her works, and as a result of his observations high problems had been suggested. He wanted even then to know many things which seem still unknownable. This want indeed never left him, and to supply it he, as life went on, diligently sought for every fact his senses could discover in the different lines of investigation he followed, and, what is more described the facts he found with an accuracy which is absolute, where he was uncertain of his facts he looked again, and to test a doubtful one he experimented. He always doubted what he could not prove. Hunter observed to find facts, and experimented to make and to prove them. The absolute necessity of accuracy of observation was so fully recognised by Hunter that he trusted nothing to memory, but wrote down what he saw at once, for, using his own words he felt that "men should be very accurate in ascertaining the truth of facts before they advance them, especially when they tend to overturn a received opinion or to establish a new one."

If Hunter was great from his industry and as an observer, he was still greater as a *thinker and reasoner*. Facts alone could not satisfy his mind. He, of necessity, speculated upon their value, and reasoned upon them with a closeness and far seeing intelligence which was surprising. He seemed as by intuition to recognise at once the full value of any fact and to be able to place it in its right position in relation to all knowledge, as a consequence, he was able, from the accumulation of the material which his observation and

experience had yielded, to elicit the principles upon which they were founded and the processes by which they were brought about. Much as Hunter did, said his friend Cline in this theatre in 1816, "he thought more. He has often told me his delight was to think." "The facility with which a man thinks," said Hunter himself, "gives him a superiority over others, few," he added, "have observed nature with more attention than myself, yet, even now, I think myself scarcely equal to the task I am undertaking—the elucidation of the economy of human life." Again, in the year 1768, "I," wrote Hunter, "was called upon to be a teacher of anatomy, but I congratulate myself that I did not become so, as it could not have failed of engaging my attention too much to admit that general attention I have been able to pay to surgery, and the necessity I should have been under to read might have occupied me too much and prevented my forming habits of established modes of thinking." Again, "what, more than all, induced me to lecture was the great advantage everyone finds by putting his thoughts into writing. A man can never tell how much he knows till he arranges his knowledge, and then he can tell how defective it is." It must therefore be accepted that deep thinking was one of Hunter's characteristics, and I can give you no better evidence of this than that quoted by Abernethy, on the authority of Clift, "that Hunter would stand for hours motionless as a statue, except that with a pair of forceps in either hand he was picking asunder the connecting fibres of some structure he was studying," and this was written of him in the year of his death.

What a picture is here presented to our minds of Hunter as an inductive thinker! The new fact displayed to view after infinite trouble. The dissector patiently reasoning out its meaning, standing for hours, in the words of an eloquent friend, before me, "patient and watchful as a prophet, as if he were sure that the truth would come—in the clearing of some mental cloud, or as in a sudden flash, with which, as in an inspiration, the intellectual darkness became light." The picture is complete. It should be painted by another Reynolds. But Hunter was more than a thinker and reasoner on facts, although as a man of science he contemplated nature with his understanding, and, as a lover of truth he kept to his facts, for he possessed to an equally high degree imagination and an intellectual foresight, with that higher degree of intellectual power which enables a man to recognise a truth directly it is enunciated, to perceive self evident facts, and through them to read the laws and fundamental principles by which nature works. He obtained his ideas as much through the reason by reflection as through the senses. In the speaking portrait above me this mental characteristic of John Hunter is displayed in a manner which genius alone could have depicted, for the thinker is clearly looking upwards as if he had heard "whisperings from the Infinite," and at the moment when one of the laws by which nature works had suddenly dawned upon him. He is manifestly looking beyond the mists which surrounded the wonderful world of life he had so long been investigating and many of the mysteries of which it had been his privilege to unveil. Indeed, Hunter's intellectual faculties had been so highly educated and were of so high an order that he was able to read the unknown truth in the known fact, and by observation and thought to work out principles and general truths which have thrown a flood of light for ever not only upon all past but upon future knowledge. And what is more, his work has been so suggestive that, whilst we his successors, adopt his thoughts we profit by the thoughts that his suggest. In all Hunter's work fact and theory were indissolubly bound together, and as a proof that his theories were good every fresh fact he discovered found its place in them. "My mind is like a beehive," said Hunter to Abernethy, one of Hunter's friends and earliest and most enthusiastic expositors, and "the simile struck me," wrote Abernethy, "on account of its correctness for in the midst of buzz and apparent confusion there was great order, regularity of structure and abundant food, collected with incessant industry from the choicest stores of knowledge." Hunter apparently had no idea of his own great intellectual powers. Abernethy records he had heard Hunter say, "I know I am but a pigmy in knowledge," and declare that he was not conscious of possessing any peculiar talent, and that if he had promoted professional knowledge it seemed to him chiefly to have arisen from his disposition to distrust opinions and to examine every subject

from nature in a manner peculiar to itself—each part of each species seems to have its monstrous form originally impressed upon it.” And, lastly, he formed the superb conception “that in nature nothing is irregular nothing is perturbed, nothing is disobedient, and everything is really regular, uniform and obedient to recognised principles.” With him the science of pathology did not mean the laws of disease in man alone or even in the whole organic kingdom, but it meant the laws of disease and malformation in the entire material world, organic and inorganic.”

These are only a few of the broad generalisations which John Hunter deduced from his careful exposition of biological facts and patient and deep thought upon their meaning. They are grand conclusions even now, if we regard them in the light of our present advanced knowledge, but they become grander when we recall the fact that biology and comparative anatomy in Hunter’s day were unknown sciences and branches of knowledge for which there was no taste. Indeed, I have out of Hunter’s own mouth already recorded how that he had as a boy pestered people with questions on natural history, subjects about which nobody knew or cared anything and it is very probable that as a man he might have said nearly the same thing. It is true that the discoveries of William Harvey, which were made known in 1620, had not only dispersed for ever the mists of vague speculation which had so grievously hung around the great central point of physiology—the circulation of the blood—but by the illuminating influence of his work had thrown a light upon many other dark spots of knowledge, which ought to have and might have enabled some of those who followed Harvey to read the lessons in his spirit. But, strange to say no such disciple appeared, and it was left for our own John Hunter upwards of a century and a half later in time, to follow in the track which Harvey had prepared, and to light a lamp which illuminated every branch of natural history and biology, which has helped succeeding generations to reach our present proud position of increasing knowledge, and which will continue to burn as an illuminating force so long as the human intellect is capable of employment.

PART III

HUNTER AS A SURGEON

Time tells me however that I must hurry on for I want before I conclude briefly to place before you the claims of John Hunter as a surgeon, as a physician, as a contributor to medical science considered as a whole, for, to his mind, what we now call medicine and surgery were inseparable, since both branches of knowledge are governed by identical laws, and the pathology of one branch is the pathology of the other. But first of all, let me assert the fact and mention it as one of Hunter’s special merits for which our profession will to him for ever be indebted—that he raised it out of the position of a poor art, based on empirical knowledge and practised too much as a trade, to establish it firmly as a high and elevating science, at the same time raising its practitioners in the social scale, and in saying this I would have it known that he did as much for medicine as for surgery, and that the physician may claim him as much as the surgeon as his own. He made our profession scientific by basing it upon the widest knowledge of the structure and functions of all living things, and by so systematising the facts which had been gathered by past experience and his own unweaned industry as to deduce from them, by his searching and luminous intellect, laws and principles for the guidance of future generations in their study and treatment of disease in any of its forms. If Hunter had come into this world for no other purpose than this he would not have lived in vain, he would have been worthy of the thanks of civilised mankind. In his teaching therefore, little else is to be found than the application of the great principles of our science to the treatment of disease and injury. “The principles of disease,” he said, “which become the object of surgery have not been sufficiently attended to, and these are what I shall chiefly consider.” As soon therefore as he proceeds to consider “the disturbances which nature works and of her cures,” he lays down the great physiological principle of *natural repair*, and states in pithy language “That all parts are capable of being restored in their kind.” “When loss of substance happens in any part, and that loss is to be restored, the parts which restore the loss or which regenerate the substance for that purpose preserve the

same disposition with which they were at first formed, the original disposition being ready to act when called upon.” The process of restoration in his mind being similar to that of formation, it is therefore to be regarded as a natural process, “for,” adds Hunter, “a sore that is going through all its natural stages to a cure cannot be called a disease.” The different processes of natural physiological repair occupied much of Hunter’s attention, and his investigations into the nature of the blood, its life and its influence on the nourishment of the system and on repair are not the least interesting portions of his work. But in this assembly of Hunterian disciples and in these days when his views are insisted upon by most surgeons there is no necessity to dwell upon them at any length, indeed, had they not been too much mixed up by Hunter with the pathological subject of inflammation, I should probably have passed them by with a brief notice. But I want on the present occasion to emphasise a fact which he himself recognised but did not make sufficiently clear, that *repair in all its forms is effected without inflammation*. That he saw this and more cannot be disputed, for I shall be able to demonstrate the truth of the assertion out of his own words, and also be able to show that he entertained the opinion that in a case of injury where inflammation takes place repair is interfered with, if not arrested. Why he in his writings failed to make these views sufficiently clear was doubtless owing to his want of knowledge as to the true causes of inflammation and I trust I may be pardoned if I assume that had he known what we now know of the effects of micro-organisms upon wounds and in the blood current he would have readily accepted the views which we now accept, that inflammation is an infective process brought about entirely by micro-organisms introduced from without and that, instead of helping it either retards or arrests repair. Under these circumstances Hunter would have been ready to adopt the view which must ere long be generally accepted and consequently taught that repair and inflammation are not only not identical, but incompatible, that repair is a *constructive* physiological process and resembles closely that of development and growth, that inflammation is a *destructive* pathological process, and is entirely due to the presence of micro-organisms introduced from without, that when inflammation attacks a wound in the process of repair it at first checks repair and later on brings about disorganising changes, and when a part repairs after it has been the seat of inflammation it does so only when the inflammatory process has been arrested.

Under these circumstances in the treatment of every wound inflammation is always to be guarded against and when present subdued since it invariably acts as a disturbing influence in the process of repair. These remarks apply as much to the healing of a wound by “quick union,” or Hunter’s “first intention,” as to one which heals by the “process of granulation or Hunter’s second intention,” or to one by “scabbing” and, I ought to add, to the restoration of any part that is undergoing repair, and which has been the seat of the inflammatory process. In support of this view I should like to quote the words of Karl Roser of Marburg, an author who has well written upon this side of my subject, and who is likely to be listened to as a German professor. “The clean, not infected, wound heals without inflammation by first intention, the infected wound, on the contrary, heals by second intention with the appearances of inflammation. In the first case healing follows immediately after the injury. In the other case inflammation intervenes between injury and healing as a disturbing complication.”

These views of repair and the influence of inflammation on the reparative process which I have just formulated, and many of which I have taught for years² are, I maintain

Hunterian”, and, if Hunter had enjoyed the opportunities we have had of learning the true cause of inflammation from the works of Pasteur and Lister, I have not a shadow of a doubt that he would have accepted the conclusions as they have been presented to you. How far he approached our present views I will now proceed to demonstrate, and I shall do so, using his own words. As a leading quotation I will select one which not only embodies the whole principle of subcutaneous surgery of which Hunter was the distinguished founder, but shows that if he had had an inkling of the true causes of inflammation how near to our present conclusions on repair and inflammation his would have been. Indeed, if we accept his sayings “that air will be injurious to man and animals by

“Practice of Surgery”

(the science which investigates the laws of disease), the causes which determine any departure from the normal type, whether of form or function, and the means which nature adopts for the healing of wounds and the repair of injuries. It was in order to understand these processes, and to search out the laws by which they were governed, that Hunter recognised the necessity of first investigating the structure of the living body, with the functions of every organ in a state of health, for he held that physiology was as essential to explain pathology as it was to explain the healthy actions of every day life. But he saw further, for, in order to understand in man the structure of his organs and their functions, he realised the wisdom of first examining the structure and vital processes of identical organs throughout the whole animal kingdom from its lower up to its higher grades. He appreciated to the full the force of Bacon's dictum, "That no natural phenomenon can be adequately studied in itself alone, but to be understood must be considered as it stands connected with all nature," or, to use Hunter's own words, "Nothing in nature stands alone, every art and science has a relation to some other art or science, and it requires a knowledge of these others, as far as this connexion takes place, to enable us to become perfect in that which engages our particular attention." If we look to Hunter's biological researches and review his conclusions, we find them very clear. He first took life as a subject, and came to the conclusion that, although "the man, the oak, and the mountain are but different modifications of the same elementary matter," "mere composition of matter does not give life for the dead body has all the composition it ever had," "that life never can arise out of, or depend on, organisation, but that organisation arises from and depends on life, and is the condition of vital action." "Life is a power superadded to matter, and is a property we do not understand, we can only see the necessary steps to it."

A seed put into a moist ground grows, but the moist ground is only a necessary attendant and not the immediate cause. The life of the seed stimulated to action by the moisture is the immediate cause of its growth. All the water in the world would not make a dead seed grow. "The same power that exists in the seed is in the egg." "The first and most simple idea of life is its being the principle of self-preservation, preventing matter from falling into dissolution, for dissolution immediately takes place when matter is deprived of life. The second idea of life is its being the principal cause of all action." "No part of the body is to be considered as a complete living substance producing and continuing mere life without the blood, so that makes one part of the compound without which life would neither begin nor be continued." "Every individual particle of animal matter is possessed of life, and the least imaginable part which we can separate is as much alive as the whole." "Blood is not only alive itself but is the support of life in every part of the body." "This living principle in the blood is in its effects similar to the living principle in the solids, it owes its existence to the same matter which belongs to the other, and is the *materia vita diffusa* of which every part of an animal has its portion, it is as it were, diffused through the whole solids and fluids, making a necessary constituent part of them, and forming with them a perfect whole." "The *materia vita* keeps up the harmony between the blood and the solids." "Mere organisation can do nothing, even in mechanics it must still have something corresponding to a living principle—namely, some power."

Hunter recognised that the chemistry of the laboratory and of inorganic bodies dealt with the same elementary substances as those of life, but he likewise recognised that the combinations of these same elements in the inorganic world differed widely from those worked up in the majesty of silence in the life department of nature's works. He proved that the life of the flesh was in the blood. And it is interesting to note how, in all his investigations into the methods which nature adopts for preserving life, he had always before him the still unsolved problem which lies behind, as to how and where the food that man takes to maintain life becomes alive, becomes, as he expressed it, animalised and vivified, for, as he said, "from living matter only living parts can be made." He was always asking himself such questions as: Does life begin after digestion in the chyle? Is the chyle alive before or after it mixes with the blood? What are the effects of respiration on the life of the blood? Indeed, I do not think that I shall be far wrong when I state my belief that it was to Hunter's attempt to solve these

and allied problems that we are indebted for the museum in the centre of which we now stand, and for the great physiological principles bearing upon the economy of life, for which all biologists and pathologists must be for ever grateful. But he was not content to trace life only in animals that move, he searched further, for "I had long suspected," he wrote, "that the principle of life was not wholly confined to animals or animal substance endowed with visible organisation and spontaneous motion, but supposed that the same principle might exist in animal substances devoid of apparent organisation and motion when the power of preservation was simply required." "I was led to this opinion," he added "in 1757, about twenty years ago, when busied in making drawings of the growth of the chick in the process of incubation. I then observed that when an egg was hatched the yolk (which is not diminished in the time of incubation) was always perfectly sweet to the very last, and that the part of the albumen which had not been expended on the growth of the animal some days before hatching was also perfectly sweet, although both were kept at a heat of 103° in the hen's egg for three weeks and in the duck's egg for four, but I observed that if an egg was not hatched that egg became putrid in nearly the same time with any other dead animal matter." This experiment suggested that eggs possessed a living principle.

To determine from other tests how far this suggestion was true, Hunter made the following experiment. "After having placed an egg in a cold mixture about zero till it froze, he allowed it to thaw, by which process it was to be supposed the preserving powers of the egg must be destroyed. He then put this egg back into the cold mixture, and with it one newly laid, and found the difference in freezing was seven minutes and a half, the fresh one so much longer time resisting the powers of cold. Again, a fresh egg, and one that had been frozen and thawed, was put into a cold mixture at 15°. The thawed one soon came to 32° and began to swell and congel the fresh one sank to 29.5°, and in twenty five minutes later than the dead one it rose to 32° and began to swell and freeze." From these experiments Hunter concluded that: fresh egg has the power of resisting heat, cold and putrefaction in a degree equal to many of the more imperfect animals, and it is more than probable this power arises from the same principle in both—"the principle of life." These experiments appear to me so simple and interesting that have been induced to bring them under your notice, for question whether, before or since, eggs have been used for more lofty purposes, and I think the conclusions which Hunter drew from his experiment are to be accepted. The tend, however, to support another principle which was dear to the mind of Hunter, and which should ever be before us as practical surgeons, and that is "the antiseptic power of life." He, however, went even beyond this for he believed that "no changes wrought in animal or vegetable bodies can possibly arise from fermentation, for the presence of life resists fermentation, and no body, while retaining its life, can possibly be acted upon by fermentation—which can only take place after the destruction of life, which is the preserving principle." Again, he demonstrated the truth that organised creation had been formed on a single plan or type, which may be traced throughout the whole animal world, and that the lower animals represent permanently the successive stages through which higher animals pass until they have attained their full and perfect development. Thus he reduced organisation to one type as he had reduced life to a single principle. But he saw further, for it seems far from his writings to infer his belief that in the gradual evolution of this type through the animal creation the idea which controlled the developmental force throughout its innumerable stages must have been pre-existent, since the idea, by virtue of which the thing made has its form and function and life, must have existed before it was revealed in its material form. He saw, with Cuvier, that the animals and plants of all periods are but different emanations from the same great thought. Hunter, however, did even more than this, for he laid it down as a law that "every deviation from that original form and structure which gives the distinguishing character to the productions of nature may not improperly be called monstrous." According to this conception of the term the variety of monsters will be almost infinite, and as far as my knowledge has extended," said Hunter, "there is not a species of animals, nay, there is not a single part of an animal body, which is not subject to an extraordinary formation. Neither does this appear a matter of chance, for it may be observed that every species has its disposition to deviate

o his observations on fossils for they are gentle to his credit as an honest thinker. Travers first brought the question alive before this College in his oration for 1838, when he showed how Hunter had pointed out the evidence which fossils afford of the alteration of the condition of the earth's surface, as dry land submerged, and by frequent allusions to the many thousand years which must have elapsed whilst the earth was the theatre of these changes he seems to have fully appreciated the necessity of an ample allowance of past time to account philosophically for the changes in question. Mr Clift, who transcribed Hunter's paper, told Mr Travers that it was originally dictated, not "many thousand years," but "many thousand centuries" and he (Clift) had the copy of the letter of the friend of Hunter (the late Major Rennell) who advised the change of expression in conformity with the popular notion of the world's age and the religious prejudices of the period.

With these references to Hunter as a geologist, biologist, physiologist, pathologist and surgeon I must bring my lecture to a close, and in doing so express a hope that we may continue in all gratitude to be inspired with the memory of John Hunter, and, as heretofore, periodically raise our voices in his honour although it may be said with truth that in the works of all who have followed his footsteps and studied in his spirit he yet speaketh. Let this Royal College of Surgeons of England which placed a tablet over the grave of John Hunter in Westminster Abbey, continue to repeat the record there engraved of their admiration of his genius as a gifted interpreter of the divine power and wisdom that works in the laws of organic life, and their grateful veneration for services to mankind as the father of scientific surgery. The harvest which has already been reaped from the good seed which was sown by Hunter has been unvalued, and the seed must be as fruitful in the future as in the past if the fields are rightly tilled by his followers. Should, however, the seed be choked or hidden for a time by weeds which have been sown by either the promoters of a passing fashion the advocates of some taking and possibly erroneous theory, or of rank empiricism, Hunter's seed, if rightly nurtured like mummy seeds when watered, will spring up with renewed vigour, to enlighten those who seek light, for it possesses a germinal principle of life which guarantees vitality.

An Address

ON THE

ANTISEPTIC MANAGEMENT OF WOUNDS.

*Delivered at King's College Hospital in the London
Post Graduate Course, Jan 18th, 1893,*

By SIR JOSEPH LISTER, BART, F.R.S.,
SURGEON EXTRAORDINARY TO THE QUEEN

(Concluded from p. 25*)

AN external antiseptic dressing, to be ideally perfect, should have four essential qualities. It should contain some thoroughly trustworthy antiseptic ingredient, it should have that substance so stored up that it cannot be dissipated to a dangerous degree before the dressing is changed, it should be entirely unirritating, and it should be capable of freely absorbing any blood and serum that may ooze from the wound.

The carbolic gauze which we formerly used did, indeed, contain a very efficient antiseptic, but this being volatile was perpetually flying off in spite of our endeavours to fix it, and it was a matter of uncertainty in how many days it might have so far disappeared from the dressing as to leave it untrustworthy. Carbolic acid had also this disadvantage as an element of an external dressing that, acting as we have seen, with peculiar energy on the epidermis it interfered seriously with cicatrization and we were obliged to interpose what we termed a protective to shield the healing wound from its action, and this gauze containing resin for the purpose of fixing the carbolic acid was not a very good absorber of blood and serum. Carbolic gauze, then, was not an ideally perfect dressing.

Corrosive sublimate had the advantage over carbolic acid of not being volatile, but it was readily washed out of gauze

or wool charged with it, and under some circumstances it proved very irritating. The discharge, passing from one part of the dressing to another took up more and more of the bichloride in its passage, and sometimes became so strong a solution of the salt as to cause vesication. I endeavoured to remedy these defects by combining the bichloride with the albumen of the serum of horse's blood¹, but though the sero-sublimate gauze answered its purpose, in so far that it contained the bichloride better stored up and in a less irritating form, it had inconveniences, especially as regarded its preparation, which induced me to abandon it.

The agent which we have found the most satisfactory as the antiseptic ingredient of the dressing is the double cyanide of mercury and zinc.² Cyanide of mercury, while it has powerful antiseptic properties, is very soluble and highly irritating, but the combination of cyanide of zinc with it has the same sort of effect, but in a much higher degree, as the albumen of the sero-sublimate gauze had upon the bichloride. The combination with zinc keeps the cyanide of mercury from being dissolved away, and also prevents it from irritating. It is, so to speak, chained down by the cyanide of zinc with which it is combined. The double salt is very little soluble in blood serum, requiring between two and three thousand parts to dissolve it, and thus a small quantity of it will last a long time in spite of a free flow of discharge through it. It thus fulfils the condition of persistent storage. It is at the same time practically unirritating, wounds heal under its immediate contact without the necessity for a protective layer interposed. Then as to the essential question of its antiseptic virtues. Small as is the quantity which serum dissolves, it proves amply sufficient to prevent bacteric development. Thus in one experiment some serum of horse's blood containing $\frac{1}{1000}$ part of the salt remained clear and odourless for more than a fortnight at the temperature of the body in spite of inoculation with putrid material and even $\frac{1}{1000}$ part prevented all growth for ten days. When mixed with serum and corpuscles, it prevents putrefaction in smaller quantity than any other antiseptic with which I am acquainted. The greater the amount of albuminoid substances in any solution, the more severely is the antiseptic tested, and when the red corpuscles are mingled with the serum, as is the case in the first twenty four hours after the infliction of a wound a much larger amount of the antiseptic is needed than with serum only. Thus four times more corrosive sublimate is required to prevent putrefaction in serum and corpuscles than in serum. Now, the double cyanide answers the purpose in half the quantity that is necessary with corrosive sublimate. As an illustration of the practical value of this material, I may mention a single experiment not hitherto published. I packed a piece of glass tube with gauze charged with 3 per cent. of the double salt and poured into it serum and corpuscles obtained by whipping pig's blood. I then inoculated one end of the saturated gauze with a drop of septic serum and kept it at the temperature of the body, with provision for preventing evaporation. After the lapse of five days I found the entire mass of gauze pure in odour and without bacteric development, as tested by microscopic examination of stained cover glass preparations of the contained blood. Meanwhile a piece of unprepared gauze similarly treated showed bacteric development within twenty four hours.

But here I must remind you of the essential difference, which must always be kept in view in considering antiseptic agents, between germicidal and inhibitory power; that is to say between the capability of destroying the life of microbes and that of preventing their growth while the agent remains in contact with them. These two properties are by no means similarly proportioned to each other in all antiseptics. Thus cyanide of mercury is far superior to the bichloride in inhibitory power, but very inferior to it as a germicide and the double cyanide of mercury and zinc, while admirable as an inhibitor is very feeble as a germicide so that we can have no security that materials charged with it may not contain living organisms. Hence if gauze charged with the double cyanide were applied dry to a wound the time might come when, if the discharge were free, the salt in spite of its slight solubility might be

¹ THE LANCET, Oct. 25th, 1883.

² This is a double salt of a very peculiar constitution. It has been specially investigated by Professor Dunstan who concludes that it has the following formula $42\text{ZnCy}_2 \cdot \text{HgCy}_2$. See Trans. Chem. Soc. 1892, p. 622. The best way of preparing it was described by Professor Dunstan in the Pharmaceutical Journal Third Series, vol. xx., No. 65.

its containing specific particles of contagion" and "that any cause that can obstruct the motion of the blood in the smaller vessels for a certain time will irritate and produce inflammation," we might fairly infer that such knowledge of inflammation and its causes was not far off. At any rate, with the knowledge he possessed he came to the following conclusions "Mechanical injuries on sound parts may be divided into two heads first, those which do not communicate externally with the air, and secondly, those which do. The effects of the first division—which do not communicate externally—on the constitution will differ according to the state of the constitution and the nature of the parts injured, if the power of healing in a part be strong, the part injured not vital, and the constitution not highly disposed to sympathy, *no material change* will take place in the constitution and the process of restoration will go on with only local effects." "Wounds which do communicate externally with the air commonly both inflame and suppurate." "The latter, when properly treated, may be brought back to a resemblance of the former, and so unite by primary healing or the first intention, by which inflammation and suppuration are prevented." "Primary healing takes its course without inflammation and is painless." "Wounds that are kept exposed do not granulate till inflammation is over." "In simple fractures union will take place independent of inflammation." "The absorption of blood when extravasated and the healing beneath the scab are both regarded as primary healing." In Hunter's recommendations as to the treatment of wounds the same general principles seem to be recognised, for he writes "In the treatment of wounds, in order to facilitate the *natural process of healing*, little is to be done except removing impediments to the natural cure." He saw with the eye of the physiologist what the eye of the poet-dramatist had previously described—

"Let nature use her own maternal means,
And we await to second, not disturb her

With these apt quotations from Hunter's own writings and lectures, there can be no doubt as to his opinions that repair and inflammation are not only not analogous processes, but that they are antagonistic, although from his want of knowledge as to the true cause of inflammation he had mixed the two processes together, and consequently had failed to make his opinions clear. It is to Hunter, therefore, more than to any man, that we are indebted for the recognition of *'of nature's resources in the cure of disease'* "He saw," wrote one of our latest departed friends, Le Gros Clark, "that nature was not to be regarded as an enemy to be combated, but as a friend with whom we may take counsel and whose efforts it is our duty to watch and assist rather than to thwart and obstruct." It is also owing to the information he laid before us in his great physiological doctrines of repair that our present knowledge of the treatment of wounds by "rest" is unquestionably based. "The first and great requisite for the restoration of the injured parts is rest, as it allows that action which is necessary for repair of injured parts to go on without interruption, and as injuries often excite more action than is required rest becomes still more necessary." "In sprains of joints," he said, "rest is the first principle." "In diseases of joints rest cannot be too much insisted on." "In the treatment of fractures the rest of the bone is the great object we have to aim at. The limb, if possible, should never be moved." "A horizontal position, with temperance, should be the first thing advised in the cure of sore legs." Hunter saw also that rest from action is an element to appreciate even in disease, for he maintained "that everything in nature that has power of action has two kinds of motion, exerted nately, and a state of rest." He saw, however further still, and said that "life cannot go on always in the same state. It must have its stated seasons of rest and action. Hence, even in the most continued diseases, and when the cause is unvaried, there will be intervals of alleviation and exacerbation." "Nature," he adds, "observing her general law, rests even in disease."

These are the great principles of practice which John Hunter laid down for our guidance and the benefit of suffering humanity. They are so intimately associated with our own daily duties that it is well for us, perhaps to be occasionally reminded as to whom we are indebted for them. The same remarks are likewise applicable to some other points of practice, for Hunter's acts were in many ways far in advance of his contemporaries. I have but time to bring

a few of them before you. In making a diagnosis of disease with the view of treatment, he advised that the history of everything relative to the disease should be known, and symptoms alone are often not enough to direct us. We should therefore get the history of it and of prior diseases, of peculiarities of constitution, manner of living, and even inquire into the temper and mind of the patient. In his investigations and treatment of disease he must often have thought, if he had not expressed the thought in words, what has been well said by a modern thinker, my friend Dr. Prentiss Smith, "that morbid processes are strictly physiological and that the origin and condition of diseases and of death must be sought by the same methods as the origin and condition of health and life." Hunter's remarks on hereditary dispositions are particularly good. "It very rarely happens that a constitution is perfectly free from a tendency to some disease. The basis of diseases is frequently laid by accident, not by producing them immediately or naturally, but by exciting some susceptibility of the constitution, or of a part into a disposition for a disease which may be latent. Disease is not hereditary, it is only the susceptibility which is so, the cause is necessary to bring it into action. It may," he adds, "be hereditary for a man to be irritable and passionate, but he will not go into a passion without some accidental cause. In some the susceptibility to a disease is very strong, then it requires only a very slight cause to bring it into action. There must, however, always be an immediate cause to stimulate the susceptibility into action." In the treatment of disease by stimulants he was very cautious. "Wine," he said, "does harm if it increases the action of the machine without giving strength, a thing carefully to be avoided. However, I have not yet made up my mind about wine." "Wine," he adds in another place, "does harm in hectic cases, increasing circulation, calling up action without strengthening, but I am not quite determined on this point. I drink no wine myself and seldom recommend it to others." I hope the total abstainers will use this information with discretion! "Women," he adds, "live a much more temperate life than men, which certainly must have considerable influence, both with regard to resisting and curing diseases." In practical surgery many most important improvements must be attributed to Hunter. For his improved treatment of aneurysm enough has been said. Stanley stamped it "as the fairest of the fruits of Hunter's genius," and yet Hunter never wrote one line to recommend the operation. The first account of the operation was given by Home in a paper published in 1793 in the first volume of the *Transactions of the Society for the Improvement of Medical and Chirurgical Knowledge*, and probably during Hunter's lifetime, but in 1786, a year after his operation, Hunter said "In December, 1785, I performed the operation in a manner different from that usually practised, and with success. The particulars are found in the *London Medical Journal*. I would only observe that in future I would advise only tying the artery in one part, and not to endeavour to unite the wound by the first intention." For many others he has never had credit, and amongst them I must place his views upon the important question of operation for cancer. "I consider," said Hunter, "that the bad success arising from amputation of the breast for cancer arose from not taking away enough. I resolved to take away much more than seemed necessary. The surgeons round me thought that I did more than what was necessary." "Perhaps it would be best always to remove the whole breast when there appears much disease, or even when the disease is not very extensive." "Whenever a gland appears tumid or indurated in the neighbourhood of a cancer, the whole that appears diseased should be removed. *Unless the whole of the diseased part can be removed* the operation for cancer will avail but little. This always should be kept in view. An inattention to these circumstances has in my opinion brought the operation into disgrace and caused people to suppose the disease to be a constitutional one." Hunter evidently regarded cancer as a local disease and advocated the practice, now generally adopted, of a free removal of the local tumour with the removal of all diseased glands. He advised "that varicose veins should be dissected out where this can conveniently be done," and for the eradication of hydrophobia he said, "mad dogs are chiefly in England. I really think that every dog here should be killed and new ones bought, or that they should perform quarantine."

To conclude my references to Hunter's works I must refer

enough of the 1 in 20 carbolic lotion to make a sort of soft mud or cream which may be applied with a camel's hair brush to parts where there is very little space between the wound and some source of septic contamination. I have by this means been repeatedly able to avoid suppuration in the vicinity of the anus as Lotherwise might have failed to do. The store of the antiseptic salt upon the skin prevents the microbes from working their way into the wound under the narrow strip of dressing alone available. There are also situations such as the pubes, where the cyanide cream applied to the hairs converts them with great advantage into a part of the antiseptic dressing.

It may be asked how it was that I obtained uniformly good results when I used corrosive sublimate solution for the purpose of producing a germicidal effect upon the gauze. For I do not exaggerate when I say that during nearly two years in which I followed this practice I did not meet with a septic failure, when I had an unbroken skin to deal with and a fair field around for the dressing. This success was no doubt partly due to the slight solubility of the double salt preventing it from being washed out of the deeper parts of the gauze. But I attribute it also to another circumstance. I invariably washed a substantial mass of the gauze which was to be applied next the wound in 1 in 20 carbolic lotion, in order to get rid of the irritating bichloride which it contained. I thus, though unintentionally, effectually sterilised not only this portion of the gauze but also neighbouring parts into which the redundant carbolic liquid soaked. And this mode of procedure, though not so perfect as the systematic moistening of the entire mass is a rough and ready way of attaining much the same result.

In changing the dressings we make it an invariable rule to cover the wound with something reliably antiseptic before washing surrounding impure parts, so as to avoid the chance of defiling the wound with them. For these washings I use the 1 in 40 carbolic lotion. As to the times for changing the dressings, it is no doubt true that that which is applied immediately after the operation might in most cases be left untouched for several days. Nevertheless when discharge is free, I prefer as a rule to remove the first dressing when the first twenty-four hours have passed. We thus get rid of the serum and corpuscles which, while they constitute the largest amount of discharge which occurs in the case, test as we have seen, the antiseptic dressings the most severely. The discharge being still moist near the wound at this period the gauze is lifted from it without disturbing it in the slightest degree, and I never knew a patient fail to express himself as feeling more comfortable when the first dressing had been changed. There are, however, special cases like a stump after amputation of the thigh, where an exception may be made on account of the disturbance of the wound that the changing of the dressing would involve.

In conclusion, I may remark that it pleases me, as the years pass, to see the hope which I expressed at the International Congress in London eleven years ago in course of fulfilment—namely, that the use of the antiseptic system would gradually spread by leavening action throughout the world. At the same time I am sorry sometimes to observe that unnecessary trouble is often taken in some directions whilst essential points are disregarded in others, so that with the best intentions the best results are not always obtained. I venture to hope that this address may be of some use to you in directing your attention to the essential conditions of success.

FRENCH HOSPITAL AND DISPENSARY—The twenty-fifth annual dinner in aid of the funds of this Institution took place at the Hôtel Métropole on Saturday last. His Excellency the French Ambassador in the chair supported by the Lord Mayor and numerous representatives of the Corps Diplomatique. The chairman alluding to the fact that he was presiding for the tenth consecutive year, announced that he had resigned the post of Ambassador and was shortly about to return to France but he assured them of his continued support of an institution which was in every respect worthy of their country. The annual report was read by the honorary secretary, Mr Ernest Ruffer, who expressed the regret felt by the governing body of the hospital and by the French colony generally at M. Waddington's approaching departure. He pointed out the extraordinary development of the charity during the last ten years, and congratulated its supporters on its steadily increasing sphere of usefulness. He concluded by an allusion to the valuable services rendered by the secretary M. Fernand Sorel, in promoting the success of the Institution. The musical arrangements were carried out in the most satisfactory manner by M. Tito Matteo.

Clinical Lecture

OR

SYMPHYSIOTOMY AT THE CLINIQUE BAUDELOCQUE DURING 1892

Delivered on Dec 7th, 1892,

By A. PINARD,

PROFESSOR AT THE OBSTETRICAL CLINIQUE OF THE FACULTY OF
MEDICINE, PARIS. MEMBER OF THE ACADEMY OF MEDICINE.

Translated by special permission from the French

By J. B. HENDERSON, M.D. BRUX., L.R.C.P. & S. EDIN.

GENTLEMEN,—A year ago, on Dec 7th, 1891, I began a lecture in this amphitheatre in the following way: "At the present time, when we find ourselves in the presence of a woman in labour having a contracted pelvis, and when we have proved either by measurement and palpation alone or by the ineffectual application of forceps the impossibility of the expulsion or the extraction of the foetus by the natural way we are reduced to choosing in order that the woman may be delivered, between the two following methods. Either to destroy the head and so terminate the delivery by natural means, or to perform Cæsarean section." And after having calculated the results obtained by the partisans of the one method and the other I continued as follows: "Thus even to-day, in spite of the considerable progress realised during fifteen years, in the presence of a case such as I have already described, we are reduced either to perform an operation which may save the mother as it certainly kills the child or to practise one which may save the child while endangering the life of the mother. Shall we always have to face this cruel alternative? Shall we be much longer condemned to the agony which one must endure in order to know what it is either to kill a healthy foetus or to make the mother run the risks (which are still formidable) of the Cæsarean section? 'I hope not,' I said. I believe that this fatality may disappear thanks to an operation—symphysiotomy—inaugurated in 1768 by one of our compatriots, a student in surgery named Sigault and practised by him for the first time with success in 1777 on the wife of a soldier named Souchoit. I can understand that this astonishes you, and you doubtless ask why to-day I place such great hopes on the revival of an operation which some of you know has been neglected for so long a time and of which some of you scarcely know the name." I then gave my reasons for thinking and speaking so, which are nothing more than the solution of the following three questions: 1. Can one by symphysiotomy obtain, without any grave lesion, a notable enlargement of the pelvis? What can be the extent of this enlargement? 2. Is symphysiotomy within reach of all accoucheurs and how ought it to be practised? 3. What are the sequelæ of the operation as regards consolidation of the pelvis, while standing and walking and in subsequent pregnancies? I ended by saying: "If I am not mistaken symphysiotomy, which had the misfortune to be suggested by a man without authority in obstetrics, by trusting in antiseptics, with the greater information which we now possess on contractions of the pelvis, guided by the sureness of our means of exploration and profiting by the perfection of our methods of operation, will become, as M. Tarnier has predicted, the complement of many cases of premature delivery and will be substituted for embryotomy and Cæsarean section in many other cases, only leaving for the latter a very restricted field where they may reign without rival."

Well, gentlemen, I wish to enquire with you whether during the year which has just passed since I spoke these words, my hopes have been deceived or realised. The moment has come for us to draw up our balance sheet and see what exactly has happened as regards symphysiotomy at the Clinique Baudelocque during the year 1892. First, it is with a satisfaction I do not attempt to conceal that I am able to say that in 1800 cases of delivery during the year I have not once had to practise embryotomy on a living foetus. Still, we have had to struggle with a considerable number of cases of contracted pelvis. In all the cases we have only performed conservative operations. I only wish to speak to-day, however, of the cases of symphysiotomy, to show them to you and to let you

all washed out of the deepest parts of the dressing, and as soon as this should be the case, living microbes contained in it would be free to develop towards the wound. In order to guard against this risk we treat the gauze before using it with a reliable germicide. That which we now use for the purpose is the 1 in 20 solution of carbolic acid, which, besides being thoroughly effective, has the further advantage that it soon flies off from the dressing and leaves nothing in contact with the wound but the unrritating double cyanide and cotton fabric.

And now I wish to correct a mistake I made in a former publication. For the purpose of destroying any microbes that there might be in the gauze I recommended a solution of corrosive sublimate 1 in 4000. Now we have seen that the 1 in 4000 sublimate lotion is not nearly so powerful as a germicide as we then supposed. But it further appears that such power as it possesses is almost entirely lost as soon as the bichloride comes in contact with the cyanide of mercury and zinc, when a curious soluble triple compound³ is formed, which has extremely slight germicidal action⁴. The triple salt seems also to be highly irritating, and thus when we used the bichloride of mercury, we failed almost entirely to obtain the object for which we employed it, and at the same time lost some of the goodness of the double cyanide, part of which was washed out in the process, while the resulting solution might cause troublesome irritation. Soon after I first described this dressing a surgeon at one of our hospitals came to me and said he had been using it and found great inconvenience from it. He had applied it to a scalp wound, and the whole of the skin covered by the dressing was excoriated. I found he had applied it soaking wet with bichloride lotion, and we are now able to understand the irritation which resulted.

It is quite unnecessary to have the gauze wet with the 1 in 20 carbolic lotion, mere dampness is sufficient. It may be conveniently moistened as follows. The gauze is commonly sold in pieces of three or six yards, folded lengthwise in eight layers. These are unrolled and half the number to be moistened are sprinkled roughly with the lotion. The wet and dry pieces are then superposed alternately and the whole rolled firmly together, and in a few minutes the entire mass will be uniformly damp. This may be done by a nurse, who then folds the gauze up in a piece of mackintosh cloth to prevent evaporation, and if the precaution is taken of turning over the edge of the jaconet so as to prevent the cotton from coming in contact with the gauze, and abstracting moisture by capillary attraction, it will remain damp for weeks together. Used in this way the double cyanide gauze may be absolutely trusted for excluding mischievous microbes, and we have seen that it contains the antiseptic element excellently stored up and that it does not irritate, and when I add that it is all that can be desired in absorbing power you will see that it approaches very closely to our ideal. Having now employed it constantly for over four years, both in hospital and in private practice, with thoroughly satisfactory results, I feel entire confidence in recommending it to you.

Here is a sample of the gauze ready for use. It is you observe, of mauve colour whereas the pure cyanide of mercury and zinc is a white impalpable powder. I have fully explained elsewhere the reasons for using a dye,⁵ but I may here shortly recapitulate them. When the pure salt is diffused in water and a piece of gauze is charged by drawing it through the liquid and dried it is found that the powder dusts out of the gauze on the slightest touch and irritates the nostrils extremely. I first remedied this defect by means of starch, and having observed that starch in solution in water becomes attached to the particles of the double salt and completely precipitated with it, it occurred to me that perhaps some colouring matter might behave in the same manner as the starch, and that thus it might be possible to dye the colourless salt and so have the means of judging, by the tint of the gauze charged with it, whether or not it was uniformly distributed in the fabric. I found on trial that various dyes did indeed behave as I hoped including colouring matters so different as Prussian blue, logwood and various aniline dyes. But, what I had not at all anticipated, it turned out that in the case of some of these dyes, when the coloured precipitate was diffused in water and the gauze was drawn through the mixture and dried without the use of

any starch, the objectionable dusting was avoided. The particles of dye, though in extremely small proportion to those of the salt, attached them, as it would appear, to the fabric.

When I last published on the subject,⁶ I recommended hæmatoxylin for this purpose. But I have since ascertained that the effect is produced still more satisfactorily by an aniline dye, the hydrochlorate of mauveine, known in commerce by the name of purified rosoline.⁷ I have here a sample of the mauve-coloured powder, the dyed cyanide. For charging gauze it is diffused with pestle and mortar in 1 in 20 solution of carbolic acid in the proportion of about thirty grains to a pint, and the gauze, which must be of thoroughly absorbent quality, is drawn, in a thickness of about eight layers, through the liquid, which is conveniently placed in a trough having a bar near its lower part, beneath which the gauze is made to pass, care being taken that the liquid is kept perpetually stirred to prevent precipitation of the salt. The gauze is then hung up to dry at the temperature of the air. The carbolic lotion is used in preference to water, both because the powder is very much more easily diffused in it and because it is desirable that any dirty material which the gauze may happen to contain may be sterilised. A very cheap kind of carbolic acid will answer, and the solution that drains from the gauze when it is hung up may be used again for the same purpose. It thus scarcely adds to the expense of the preparation.

This is a very simple process. For a whole year I prepared my own gauze, for use in hospital as well as in private practice, before I had satisfied myself completely as to its value. For hospital use I would advise that the gauze should be prepared in the institution, so as to save the manufacturer's charges. In that case it may be taken down and wrapped in mackintosh when only partly dry, avoiding the trouble to the nurses in moistening it.

Gauze may also be easily charged at a few minutes' notice for emergency in private practice. I have here a six yard piece of unprepared absorbent gauze folded lengthwise in eight layers. I soak this thoroughly with 1 in 20 carbolic lotion, and dust some of the powder roughly over one surface with a pepper box. I then roll it together, and kneading it for a minute or two with the fingers produce, as you see, a sufficiently uniform diffusion of the salt throughout the mass, as indicated by the colour.⁸ If this were done by a nurse before the commencement of an operation, and the wet gauze were wrapped in a folded sheet to absorb redundant moisture, it would be ready for use when required. A six yard piece would be an ample dressing for many cases. Now I see by the amount that has gone from the pepper box that not more than one fifth of an ounce has been used, and as the dyed cyanide is supplied at 20s. per pound, this implies a cost of only 3d., so that it cannot be regarded as expensive.⁹ If you have no absorbent gauze at your disposal, linen rags, which are excellent in absorbing quality, may be quite well charged in a similar manner. This old towel which has been so prepared, if folded a few times, would make a perfectly satisfactory dressing. Bandages which it is desirable to render efficiently antiseptic, such as one that is to be applied next the skin for keeping down the soft parts in a stump after amputation of the thigh, may be charged on the same principle.

When a free discharge is anticipated, we apply a piece of thin mackintosh, sponged with carbolic lotion, over the exterior of the dressing, to prevent the blood and serum from passing directly through it. Thus arrangement no doubt interferes somewhat with the inspiration of the discharges by evaporation, but this is a matter of indifference when the dressings are efficiently antiseptic.

There is another use to which the dyed cyanide powder may be often advantageously put—namely, treating it with

⁶ *Ido loc. cit.*

⁷ This dye may be obtained from Messrs. Meister, Lucius and Brühl of Hoechst-on-Main. I may here publicly express my thanks to Mr. Perkin to whom the world is indebted for the aniline dyes, for his kindness in ascertaining for me the chemical composition of rosoline. It is used in quantity equal to 1 per cent. of the weight of the double cyanide and is applied in water solution in which the salt, after being freed from excess of cyanide of mercury by repeated washing, but before it has been dried is thoroughly diffused by stirring. The salt as it precipitates carries the dye down with it and is afterwards dried at a moderate temperature.

⁸ A pair of leather gloves may be worn to avoid staining of the hands, or the dye may be washed from the fingers with spirit of wine.

⁹ I found on weighing this piece of gauze when it was dry that it was quite needlessly heavily charged containing 7 per cent. of the salt instead of 3 per cent. which is that ordinarily used. Thus the salt required for such a dressing does not really cost 14d.

³ See Varet, Comptes Rendus 1883, vol. civ. p. 1080

⁴ For the determination of this fact I am indebted to my colleague Professor Crookshank.

⁵ THE LANCET, Jan 4th 1890

mental, 15.4 cm., occipito-frontal, 11.1 cm., sub-occipito-bregmatic, 9.3 cm., sub-occipito-frontal, 9.8 cm., biparietal, 8.2 cm., bitemporal, 7.5 cm. The child was born in a state of apparent death, but revived in two minutes without insufflation. He appeared feeble. He was placed in an incubator at 35 C (95 F). Breathing oppressed all day. On Mar 3rd there was cyanosis. He did not suck, but took and kept down milk which was given with a spoon. On Mar 4th he was in the same condition, the respiration was accelerated, the cyanosis persisted, and milk was rejected. He died on the 5th at 6 A.M. At the necropsy at 6 P.M. the weight was 1950 grm. (over 4 lb.) all the viscera appeared healthy, no fracture or fissure, Wormian bones. Puerperal condition pathological, abscess of left labium majus incised and drained on the seventeenth day, without any connexion with the operation wound, which united by first intention. The patient rose on the twenty-sixth day and walked without pain. She went out on June 23rd in perfect condition. When seen on Dec. 7th no trouble in walking or micturition was observed.

CASE 5. May 29th, 1892 (Pinard) —A— aged thirty-eight, six confinements. Pelvis annular, promonto-subpubic diamer 9.3 cm. First confinement in 1835 at term, terminated by basiotomy of the living foetus after seventy-three hours of labour and an application of forceps made by M. Pinard. Weight of foetus 3520 grm. (nearly 8 lb). Second confinement in 1837 induced at seven months and a half. The child died during labour. The third confinement occurred in 1838, was induced at seven months and was terminated by an application of forceps at the entrance to the pelvis. The boy weighing 2200 grm. (nearly 5 lb) died during the night. Biparietal diamer 8.6 cm. The fourth and fifth pregnancies were miscarriages at two months and a half and three months respectively. The fourth confinement took place on Mar 29th, 1892, at the Clinique Baudelocque. Last monthly period occurred from Sept 14th to 17th, 1891. Presentation of vertex, not engaged, in left transverse position. Considering the history M. Pinard decided to wait till term and practise symphysiotomy before making any attempt at extraction. Onset of labour was induced on Mar 28th at 5 A.M. by premature rupture of the membrane—dilatation was complete on the 29th at 6 A.M. At 10.10 A.M. symphysiotomy was performed by M. Pinard (ten minutes), spontaneous separation of 2.5 cm. At 10.33 A.M. the forceps were applied in the left transverse diameter extraction being easy at 10.40 (during which the separation extended to 4.5 cm.) of a boy weighing 3110 grm. (over 6 lb) crying at once and with the following cephalic diameters: Occipito-mental, 13.2 cm., occipito-frontal, 11.5 cm., sub-occipito-bregmatic, 10 cm., sub-occipito-frontal, 10 cm., biparietal, 9.1 cm., bitemporal, 8.2 cm. The infant was suckled by the mother assisted at first by a wet nurse. He weighed when leaving the clinique, on the thirty-first day, 3350 grm. (over 9 lb). Puerperal condition normal only twice—the second and seventh day—did the temperature rise to 33 C (100.6 F). Union by first intention. The patient rose without permission on the sixteenth day but experienced no bad result. She went out on the thirty-first day in perfect condition. When seen on Dec. 7th she appeared to have no trouble in walking or micturition. Child healthy.

CASE 6. June 29th, 1892 (Pinard) —F— aged thirty-two, primipara, height 1.35 m. (4 ft. 5 in.). Pelvis generally contracted, promonto-subpubic diameter 9 cm. Last monthly period occurred from Oct. 9th to 12th, 1891. Presentation of vertex in left transverse position. On June 28th, considering the information furnished by palpation, by measurement of the promonto-subpubic diameter and by the exploration of the entire pelvis, M. Pinard decided to induce labour and to practise symphysiotomy before attempting to extract. Tarnier's bag was introduced at 10.30 A.M. on the 23rd and Champetier's bag at 5.30 A.M. on the 29th. The membranes were ruptured, dilatation complete at 9 P.M. Extraction of the bag caused a tear of the left side of the vestibule, necessitating the application of two pressure forceps. At 9.15 P.M. symphysiotomy was performed by M. Pinard (three minutes), separation 3.5 cm. At 9.24 P.M. on the application of forceps in the left transverse diameter, easy extraction was effected at 9.42 P.M. (during which the separation amounted to 6.2 cm.) of a boy weighing 2720 grm. (over 5 lb.) crying at once and with the following cephalic diameters: Occipito-mental, 13 cm., occipito-frontal, 11 cm., sub-occipito-bregmatic, 10 cm., sub-occipito-frontal, 10.3 cm., biparietal, 9.4 cm., bitemporal, 8.2 cm. Brought up by a wet-nurse, this child weighed when left on the fifteenth day 4000 grm. (8.8 lb.)

Puerperal condition normal. Union by first intention. The patient rose on the twentieth day and was able to walk without pain or difficulty. She is at present a nurse in the hospital. The child when seen on Dec. 7th was healthy.

CASE 7. July 7th, 1892 (Pinard) —A— aged twenty-three, primipara, height, 1.42 metres (4 ft. 8 in.), pelvis annular, promonto-subpubic diameter 10.4 cm., last monthly period from Sept 25th to 30th, 1891, vertex presenting in left transverse position. On July 6th, considering the information furnished by palpation M. Pinard induced labour with the aid of Tarnier's bag which was replaced on the 7th at 4 A.M. by one of Champetier's bags. Dilatation was complete at 10.15 A.M. At 10.40 A.M., after manual exploration symphysiotomy was performed by M. Pinard (seven minutes), with spontaneous separation of 1 cm. At 10.51 A.M. artificial rupture of membranes and application of forceps in left transverse position were followed by the extraction at 11.4 A.M. (during which the separation reached 5 cm.)—thanks to a second application of the forceps the former threatening to slip—of a living boy weighing 3300 grm. (over 7 lb) with the following cephalic diameters: Occipito-mental, 13 cm., occipito-frontal, 12.2 cm., sub-occipito-bregmatic, 11 cm., sub-occipito-frontal, 12 cm., biparietal, 10 cm., bitemporal, 9 cm. Brought up by a wet-nurse, this child weighed when left on Sep. 2nd 4340 grm. (about 9½ lb). Puerperal condition slightly pathological the temperature oscillating about 33.5 C (101.4 F) during the first seven days. Union by first intention. The patient rose on the twenty-fourth day and could walk without pain. When seen on Dec. 7th she had no trouble in walking or on micturition. Child healthy.

CASE 8. July 30th 1892 (Lepage) —M— aged twenty-six, two confinements, pelvis annular, promonto-subpubic diameter 9.7 cm. First confinement in 1837, at term, spontaneous of a large child, now living and healthy. Second confinement at the Clinique Baudelocque on July 30th, 1892. Last monthly period from Oct 1st to 5th 1891. Vertex presentation in left transverse position, head not engaged. When admitted on July 30th at 4.44 A.M. dilatation was nearly complete. Labour began on the 29th at 11 P.M., membranes intact. At 6.45 A.M. artificial rupture of membranes. At 7 A.M. M. Lepage reports "Dilatation complete, head very high in left transverse position, fluid green, prolapse of the cord, heart sounds dull and irregular. After an ineffectual application of the forceps (traction during twenty minutes), M. Pinard having been communicated with, M. Lepage performed symphysiotomy at 10 A.M. (thirteen minutes) the section of the symphysis was from below upwards, being followed by spontaneous separation of 26 mm. On the application of the forceps an easy extraction was effected at 10.18 A.M. (during which the separation reached 5 cm.) of a boy weighing 4000 grm. (8.8 lb). He was born apparently dead, was insufflated and revived ten minutes afterwards having the following cephalic diameters: Occipito-mental, 13.1 cm., occipito-frontal, 11.5 cm., sub-occipito-bregmatic, 9.8 cm., sub-occipito-frontal, 11.3 cm., biparietal, 9.5 cm., bitemporal, 8.7 cm. Brought up by a wet-nurse the child weighed when he left on Sept. 2nd 4090 grm. (nearly 9 lb). Puerperal condition pathological, abscess of the right labium majus incised and drained on the tenth day without any connexion with the operation wound, which united by first intention. The patient rose on the thirtieth day. Was discharged on Nov 5th in perfect condition. When seen on Dec. 7th no trouble in walking or micturition was noticed. Child healthy.

CASE 9. Sept 13th, 1892 (Varnier) —B— Two confinements. Height 1.39 metres (4 ft. 6½ in.), pelvis rachitic annular, promonto-subpubic diameter 9.2 cm. First confinement in 1889 at term terminated by basiotomy of a dead foetus. The patient was brought in on a stretcher with dilatation complete, membranes ruptured, prolapse of cord and of anterior arm, head not engaged in left transverse diameter. M. Varnier had to compress the head twice. The extraction only became possible after putting back the anterior arm and it was necessary to practise Ribemont's method to extract the trunk. Weight of the child 3350 grm. (over 7 lb). Second confinement Sept 13th, 1892, at the Clinique Baudelocque. Last monthly period Dec. 10th to 15th, 1891. The patient entered the hospital on July 26th pregnant about seven months foetus living, no fixed presentation, the head was retained below by the aid of the "entoclique" binder from Aug 15th. At this time the palpation showed that there was a disproportion. M. Pinard left for his holiday and gave M. Varnier (his assistant)

appreciate the results. Thirteen symphysiotomies have been practised in the Clinique Baudelocque during 1892—eight by myself, the rest by my assistants. I did the first on Feb 4th, the last was done on Nov 14th. I will show you the thirteen women, for they have been very willing to come back to-day. In this way you may judge of the immediate and subsequent results of symphysiotomy. I will present them in chronological order, giving with each a short *résumé* of the notes of the case.

CASE 1 Feb 4th, 1892 (Pinard) —B—, aged thirty two. She has had two confinements. The pelvis was canalculated, the promonto-subpubic diameter 9.7 cm. The first confinement took place on July 13th, 1886, at term. The presentation was of the shoulder, there was prolapse of the cord, the fœtus was dead and macerated. Embryotomy was performed. The head could only be extracted after basiotripsy. The patient went out thirty two days afterwards. The second confinement took place on Feb 3rd, 1892. The last monthly period was from May 1st to 6th, 1891. The fundus uteri was 36 cm above the upper border of the symphysis pubis. There was hydramnios, the fœtus was mobile, with a tendency to present by the breech—it appeared to be large. Mensurative palpation showed a considerable disproportion. Champetier's bag (*ballon Champetier*) was introduced at 7.30 P.M. On Feb 3rd at 12.15 (midnight) dilatation was complete and expulsion of the bag imminent. At 12.30 A.M. chloroform was given and the bag extracted, the pouch of membranes being found intact. Many unsuccessful attempts were made to bring down the head by external manipulation, the fœtus presenting by the breech in the right transverse diameter. M. Pinard then decided to extract by the feet after a preliminary symphysiotomy. At 12.50 A.M. the incision was begun, spontaneous separation after symphysiotomy of 1 cm. being effected, followed at 1.15 A.M. by artificial rupture of membranes and beginning of extraction. At 1.20 A.M. the breech was outside the vulva. At 1.24 the head was extracted by Champetier's method, the extraction being difficult, accompanied by two jerks, the latter of which was the more noticeable. The separation was not measured. Delivery was effected. At 1.45 A.M. the parts were sutured and the dressings fixed by a plaster bandage. The child weighed 3350 grm. (over 7 lb.) and measured 52 cm. It was apparently dead, but was quickly resuscitated by simple friction. There was deep depression of the right parietal bone posteriorly, so that, while the biparietal measurement was 9.8 cm, the diameter, which went from the bottom of the depression to the protuberance on the anterior portion of the parietal bone, measured only 8.9 cm. The child died on Feb 6th (third day), having presented the classical symptoms of meningeal hæmorrhage. (The head is preserved in the museum.) The puerperal condition was normal, only once on the fifth day did the temperature reach 100.6° F (38.2° C). There was union by first intention. The patient rose on the twenty first day and was able to walk without pain. There was no abnormal mobility. She was seen on Dec 7th, when there was found to be no trouble in walking or micturition.

CASE 2 Feb 22nd, 1892 (Pinard) —G—, primipara. The pelvis was flattened, the promontory accessible. The confinement took place at term. She was admitted at 9.15 P.M. on Feb 24th, the os being the size of a franc piece, the membranes were intact and tense. The fundus uteri rose to 47 cm above the upper border of the symphysis pubis. The ovum was large, there was presentation of the vertex in the left transverse diameter, not engaged. The fœtus was living. There was artificial rupture of the membranes at 10.15 P.M. on Feb 24, 400 cc of liquid escaped. Complete dilatation took place at 4.30 A.M. On the 25th the head was found to be fixed, but not engaged. At 7.30 A.M., the head not being yet engaged in spite of very good contractions, M. Lepage made a first application of the forceps under chloroform. Traction was made during fifteen minutes without result. At 8.4 A.M. a second application of the forceps was made, the tractions lasted three minutes only, no progress. M. Pinard arrived at 9.30 A.M. Chloroform having been given, symphysiotomy (nineteen minutes) was performed, giving immediately after the section and spontaneously a separation of 1 cm, which the abduction of the thighs increased without difficulty to 3 cm. There was a third application of the forceps, when extraction was extremely easy in four minutes of a boy (living) weighing 4630 grm. (over 10 lb.), measuring 53½ cm (20½ in.), of which the cephalic diameters were: Occipito mental, 14.3 cm., occipito-frontal, 12.7 cm., sub-

occipito-bregmatic, 10 cm., sub-occipito-frontal, 11.3 cm biparietal, 9.3 cm., bitemporal, 8.7 cm. During the engagement and descent of the head the separation of the pubes reached 6.1 cm. The child weighed on March 15 5970 grm. (over 13 lb.). The puerperal condition was normal only four times—viz., on the third, fifth, tenth and fourteen days—did the temperature reach 38° C (100.2° F). There was union by first intention. The patient rose on the thirty third day and was able to walk without pain, there was abnormal mobility. She was seen on Dec. 7th, when there was no trouble in walking or micturition. The child living and healthy, and at present with a nurse.

CASE 3 March 23rd, 1892 (Pinard) —P—, aged thirty. She has had four confinements. The pelvis was annular, the promonto-subpubic diameter 9 cm. Her first confinement took place in 1887, at term. There was intervention after administration of ether, child stillborn. The second confinement took place in 1888, induced at eight months. A child died on the third day. The third confinement occurred in 1890, at term. There was an application of the forceps. M. Fochier, who extracted a boy weighing 3220 grm. (ab 7 lb.), but having a biparietal diameter of only 7 cm. A child died after fifteen days. There was a fourth confinement on March 23rd, 1892 (Clinique Baudelocque). The last monthly period occurred June 30th to July 2nd, 1891. The fundus uteri rose to 36 cm above the upper border of the symphysis. There was presentation of the vertex in the left transverse diameter (after external version and application of band). Tarnier's bag was introduced on March 21st, 10.50 A.M., the expulsion took place at 1 P.M. On the 22nd at 5 A.M., Champetier's bag was introduced. At 11 A.M. dilatation was complete, when the bag was extracted under chloroform and the membranes ruptured. After an hour (12.15) M. Fochier made successively oblique applications of Tarnier's forceps, then M. Pinard made a direct application—all without success. At 12 symphysiotomy was performed (seven minutes). The pubes separated spontaneously 1 cm., by abduction of the thighs separation was brought to 4.8 cm. At 12.50 a fourth application of the forceps was made, during which the separation amounted to 6½ cm. At 1 P.M. extraction was effected of a boy weighing 2730 grm. (over 5 lb.), whose cephalic diameters measured immediately after birth: Occipito mental, 12.7 cm., occipito-frontal, 11.8 cm., sub-occipito-bregmatic, 10.4 cm., sub-occipito-frontal, 10.6 cm., biparietal, 9.7 cm., bitemporal, 7.9 cm., sub-mento-bregmatic, 9.5 cm. The child was born in a state of apparent death, but rapidly revived. The child weighed on April 15th 3000 grm. (6.6 lb.). The puerperal condition was normal. There was union by first intention. The patient rose on the twenty ninth day, and was able to walk without pain, there was no abnormal mobility. She was seen on Dec 7th, and had then no trouble in walking or micturition. The child is living and healthy.

These three women were presented to the Academy of Medicine at its meeting on May 21st, and I read the *résumé* of the cases at the meeting of the Obstetrical Society of France.

CASE 4 May 3rd, 1892 (Varnier) —R—, aged twenty six, four confinements, height 1.46 m (4 ft 9 in.). Pelvis rachitic, annular, promonto-subpubic diameter 9.8 cm. First confinement in 1886, terminated by embryotomy after two days' labour. Second confinement in 1887, induced at about eight months, terminated by version when dilatation complete (head, with prolapse of cord, hands and one foot), girl, born in a state of apparent death, revived without sufflation, weight 2400 grm. (under 5 lb.), died next day. Third confinement in 1890 induced at eight months, terminated by basiotripsy. Fourth confinement on May 3rd, 1892 (Clinique Baudelocque), last monthly period Aug 3rd to 5th, 1891. The fundus uteri rose to 29 cm above the upper border of the symphysis, presentation of the vertex in left transverse diameter. Considering the antecedents, M. Pinard decided to induce labour and to practise symphysiotomy before making any attempts at extraction. Champetier's bag was introduced on May 3rd at 5.40 A.M., at 10.30 A.M. dilatation was complete, membranes intact, no prolapse, head in left transverse diameter not engaged. At 11.48 A.M. symphysiotomy was performed by M. Varnier. Spontaneous separation of 3 cm. occurred, followed by artificial rupture of membranes. At 11.58 A.M., on the application of forceps in the left transverse diameter, the extraction was easy (during which the separation did not increase more than half a finger's breadth) of a boy weighing 2130 grm. (about 4½ lb.), whose cephalic diameters were: Occipito-

infant was insufflated and revived, but died at 1 A.M. on Nov 14th, the cephalic diameters were as follows: Occipito-frontal, 13.6 cm., occipito-frontal, 11.2 cm., suboccipito-frontal, 10.7 cm., biparietal, 9.5 cm., bitemporal, 8.4 cm., the application of the forceps was irregular, oblique, the interior frontal region presenting a deep depression produced by the anterior blade, this depression disappeared in the evening at the same time as convulsive movements of the left half of the face appeared, the head, which is preserved in the museum, will be described later, puerperal condition temperature oscillating about 38°C (100.4°F) the first five days, union by first intention, the patient rose on the twenty second day, she had no trouble in walking or on micturition, is still under observation.

You have just seen these thirteen women, and you are able to report that their general condition leaves nothing to be desired. The only evidence of the operation that they have undergone is a small cicatrix, scarcely visible, in the middle of the pubic region. In each the pelvis is as firm as before the operation. There is no trouble in micturating or in standing. The result is therefore as satisfactory and as complete as possible on the maternal side. We have been less happy in the case of the infants, for although all were extracted living I have only been able to show you ten, all indeed equally well, but the other three died—the first on the third day after birth (Case 1) the second on the second day after birth (Case 4), and the third in sixteen hours after birth (Case 13). If we look for the cause of death in each case, we see that in the first death was produced by fracture of a parietal bone at the moment of extracting the after-coming head. The preliminary separation of the pelvis was certainly not sufficient, considering the size of the head and the amount of pelvic contraction. This is an extremely important point, to which I will return. The second child died of congenital feebleness for it showed no lesion at the necropsy. Although its weight at birth was 2130 grm (about 4½ lb.) its vitality was rudimentary. Its cry was feeble and its abdomen was large. Respiratory troubles soon appeared and it died of cyanosis. Neither the operation nor the operator can be blamed. The only one who might be considered culpable is myself, for I might be reproached for interrupting pregnancy too soon. But I was led to act thus because of what happened at previous confinements: first, at term, embryotomy, second, induced at eight months, foetus dead, third also at eight months, basiotripsy. I shall have to return to this point. As to the third child, it succumbed like the first, to a fracture, this time of the frontal bone. Although the spontaneous separation of the pubes before extraction was 3 cm., the head engaged with difficulty, for it was large (biparietal diameter 9.3 cm.), but especially because the application of the forceps was irregular (oblique). This is a point which we must not forget presently. Such are the results furnished by symphysiotomy in this clinique since Feb 4th, 1892.

Let us now consider the following three questions: 1. What has our experience taught us? 2. What place ought symphysiotomy to occupy amongst obstetrical operations? 3. What are and what will be its relation to other operations?

1. *What has our experience taught us?*—We have learnt, from the thirteen cases which have been observed in this clinique, that the results obtained on the cadaver can be obtained in the same way on the living patient and that the geometrical formulae of Professor Farabeuf are perfectly exact. We have learnt that the method of operation which we recommended and which we have employed, and which I ask permission to repeat briefly, renders the operation easy and absolutely protects the organs which ought not to be injured. All antiseptic precautions having been taken and the surgical and obstetrical instruments prepared, the woman should be placed on her back near the side of a firm bed of moderate height, so that one may command directly from above the median line, which has to be incised. In the case of the cadaver, one can stand on the right side to perform symphysiotomy. On the living it is better, on account of the development of the abdomen, to stand between the limbs. I have always done so on the living. An incision should be made in the median line, and exactly in this line, of the integuments and the prepubic adipose tissue for an extent of about 8 cm. the incision stopping above the clitoris. The recti in the upper part of the incision and immediately above the symphysis should be separated in order to allow the index finger to penetrate into the prevesical cavity and protect the bladder. This finger plays a most important rôle for me, it protects, it gives information. It protects the bladder by its dorsal aspect, it

often feels the pad of the symphysis (but not always, for this is often so very slightly prominent that it cannot be appreciated) and thus renders the section easy. As soon as the bistoury has penetrated into the symphysis it is this finger on which its blunt point strikes, and that keeps a record of its progress down to the last fibres of the subpubic ligament. The finger being thus in the prevesical cavity, the symphysis must be incised from above downwards, and from before backwards, by many touches of the bistoury, allowing the latter to penetrate where it finds least resistance. As soon as we are within the symphysis the bistoury must be allowed to guide, so to speak, and not be compelled to follow a straight line. Immediately after cutting the symphysis a complete section of the subpubic ligament should be made. For this section the precaution must be taken of introducing a sound into the urethra so as to incline the latter down to the side, then the ligament must be attacked with caution by small cuts, as if cutting it fibre by fibre. The finger shows the progress accomplished, and as a general rule, when the finger learns that only a few fibres remain, like a small resisting cord, this cord breaks and the spontaneous separation, which had been only a few millimetres, suddenly increases and reaches two or three centimetres. A careful abduction of the thighs then shows that a further separation can be easily obtained. I cannot too often repeat that before all obstetrical attempts one must be sure that the section is complete so that the foetus may have nothing to overcome by violence and at the peril of its life—that is to say, the pubes must be separated for at least 4 centimetres. If the abduction of the thighs is not sufficient to produce this separation, the registering separator, which has been made for us by M. Collin and which I show you, introduced between the two surfaces of the section, will easily produce this desirable and indispensable result. This being done, the wound must be closed with a sponge and antiseptic gauze or wool. You see that I reject, completely and absolutely, subcutaneous section, the incision of the symphysis from below upwards and the incision from behind forwards. You observe especially that I am in complete opposition to those who advocate incomplete section or who leave the subpubic ligament. I am convinced that if I had obtained a preliminary separation of 4 cm. in my first operation before extracting the foetus instead of leaving to the after-coming head the duty of separator I should have obtained a better result. So much for the method of operation in symphysiotomy itself. I now examine an obstetrical question and I say that both before and after symphysiotomy it is preferable to have a vertex presentation. An application of forceps is better than an extraction by the feet, at least, so I think. But, here, again, I cannot too often repeat that the application of forceps ought to be exact. The hand should be thoroughly introduced so as to place the first blade in the middle of the pre-auricular region, if the head is not flexed it should be first flexed with the hand. Nothing is easier. That being done the other blade should be introduced without displacing either the first blade or the head. Remember that when the two blades are introduced and placed, if they are not on the same plane and if you are obliged to make an effort to articulate them, the blades are badly placed, the head is wrongly seized and soon in pulling you will without doubt, make the head endure enormous local pressure and produce fractures. You remember what happened in Case 13. Well, then the necessity for an equal application of forceps on a flexed head after as well as before symphysiotomy is absolute. Then after section of the symphysis I prefer to intervene and not to trust to uterine contractions alone to expel the foetus, also after the extraction of the foetus I do not prolong the period of delivery. If after a quarter of an hour the placenta is not detached I practice artificial delivery, for the patient under the influence of chloroform is liable to hemorrhage and the anaesthesia must be continued till the sutures are completed. Immediately after the delivery I advise you to wash out the uterus. When the water returns clear and the uterus is well retracted I introduce into the vagina iodoform gauze, then I clean the wound with a sponge and a 5 per cent. carbolic lotion and proceed to suture the soft parts. The symphyses being brought together and well in contact, I place four deep silver sutures (which touch the anterior surface of the pubis) and four superficial ones and then cover with iodoform and iodoform gauze. After this, the legs being brought together and held in position by a bandage, the woman is placed in a bed which I have had made—a bed which, by means of its two lateral and concave tampons, enables the pelvic bones to be kept in

the responsibility of fixing the date for symphysiotomy M Varnier decided to wait till term. Labour began on Sept 12th at 7 P.M., dilatation was complete at 5.40 P.M., symphysiotomy was performed by M Varnier (six minutes), separation to 3.5 cm. was induced by abduction of the thighs, spontaneous rupture of membranes, at 5.49 P.M. the application of forceps in the left transverse diameter was followed by extraction at 5.55 (during which the separation reached 7 cm.) of a boy weighing 3200 grm (7 lb.), who cried at once and had the following cephalic diameters: Occipito mental, 12.5 cm., sub-occipito bregmatic, 9.8 cm., sub-occipito-frontal, 11.4 cm., biparietal, 9.5 cm., bitemporal, 8.5 cm., circumference, sub-occipito-bregmatic, 34.0 cm., circumference, sub-occipito frontal, 36 cm. Brought up by a wet nurse, this child weighed when discharged on Oct 16th 3630 grm. (over 8 lb.) Puerperal condition. Three times only, on the third, fourth and fifth days, did the temperature reach 38.5°C (101.3°F). There was union by first intention. The patient rose on the nineteenth day and was able to walk alone and without pain. It is to be noted that during the extraction there was produced (to the left of the urethra, which was intact as catheterism proved) a longitudinal tear in the anterior wall of the vagina, which allowed the index finger to pass from the vagina to between the separated pubes. The operation wound communicated with the vagina, which was tamponed with iodoform gauze left in position for three days. The patient left on Oct 16th in perfect condition. There was no abnormal mobility, or trouble in walking or micturating, the vaginal cicatrix could be clearly felt by the finger, and was not painful, when seen on Dec 7th the same condition was observed, the child was healthy.

CASE 10 Oct. 1st, 1892 (Pinard) —F—, aged twenty five. The following are the notes. Two confinements, pelvis flat, promonto subpubic diameter 10 cm. First confinement in 1891, albuminuria and eclampsia, twins, extraction by the feet, the children being alive, one died on the fourteenth day and the other at four months, one weighed 2300 grm. (5 lb.), biparietal 8.5 cm., the other 1980 grm (over 4 lb.), biparietal 8.4 cm. Second confinement Oct. 1st, 1892 (Clinique Baudeloque), last monthly period Dec 15th to 18th, 1891, presentation of the vertex, not engaged, in left transverse position, labour began on Sept. 29th at 7 P.M., at 9 P.M. on Oct 1st, dilatation having remained stationary for twelve hours (as the size of a five franc piece), the membranes were ruptured, the head scarcely engaged, very much inclined on the posterior parietal region midway between flexion and extension, M Varnier applied a Champetier's bag, and when the dilatation was complete, after extraction of the bag distended to the maximum, he applied the forceps in the left transverse diameter, which only accentuated the deflexion, he then made a second application of the forceps, flexion was obtained, but in spite of powerful traction no engagement was produced, not wishing to make a forcible application, M Varnier consulted M Pinard, who at 10.50 P.M., things being still in the same condition, performed symphysiotomy (twelve minutes), followed by immediate separation to 3 cm., at 11.9 P.M., on the application of the forceps in the left transverse diameter, easy extraction was effected (during which separation amounted to 4.5 cm.) of a boy weighing 3220 grm. (7 lb.), with the following cephalic diameters: Sub-occipito bregmatic, 9.3 cm., sub-occipito frontal, 10.6 cm., biparietal, 9 cm., bitemporal, 7.8 cm., circumference—sub-occipito bregmatic, 31 cm., sub-occipito-frontal, 32 cm., brought up by a wet-nurse, the child weighed when he left 3420 grm. (nearly 7 lb.), puerperal condition normal, union by first intention, the patient rose on the nineteenth day, walking alone and very well, she left on Nov 6th in perfect condition, when seen on Dec. 7th she had no trouble in walking or on micturition, child healthy.

CASE 11 Oct. 6th, 1892 (Pinard) —B—, aged twenty eight. The following are the notes. Two confinements, pelvis rachitic, annular, promonto subpubic diameter 10 cm. First confinement in 1889, at term, terminated by an application of the forceps, the child died on the twenty seventh day of convulsions, bearing still the traces of the forceps. Second confinement on Oct. 6th, 1892 (Clinique Baudeloque), last monthly period, Dec. 26th to 29th 1891, presentation of the vertex, not engaged, in left transverse position, labour began on Oct. 5th at 3 A.M., spontaneous rupture of membranes at 7.20 P.M., dilatation complete at 11.55 P.M., the forceps were applied in left transverse diameter at the pelvic entrance by Dr Wallich who, in spite of energetic traction, could not engage the head,

after making a manual examination, M. Varnier, not wishing to make a second application which would involve force, consulted M. Pinard, who, being exactly informed as to the condition of the mother and foetus, advised delay, at 10 A.M. the temperature being 38.8°C (102°F) and things being still at the same point, M. Pinard performed symphysiotomy (two minutes) resulting in immediate separation to 3 cm. on the application of the forceps in the left transverse diameter extraction was easily made at 10.25 A.M. (during which the separation reached 5.8 cm.) of a boy weighing 3750 grm (over 8 lb.), the infant was born apparently dead, but rapidly revived, and had the following cephalic diameters: Occipito mental, 13.6 cm., occipito frontal, 11.0 cm., sub-occipito bregmatic, 10.3 cm., sub-occipito frontal, 11.5 cm., biparietal, 8.4 cm., bitemporal, 7.9 cm. brought up by a wet-nurse, this child weighed when he left on Nov 15th 4840 grm (about 9½ lb.), puerperal condition temperature oscillated about 38°C (100.4°F) without exceeding 38.5°C (101.3°F), during the first twelve days union by first intention, the patient rose on the twenty-fourth day (Oct. 29th) and left on Nov 15th in perfect condition when seen on Dec 7th, she had no trouble in walking on micturition, child healthy.

CASE 12 Oct. 21st, 1892 (Wallich) —M—, 7 following notes were taken. Three confinements, pelvis annular, promonto-subpubic diameter 10.5 cm. First confinement spontaneous, at term, child living. Second confinement spontaneous, in 1889, child large, died during labour. Third confinement on Oct. 21st, 1892 (Clinique Baudeloque), last monthly period Jan. 4th to 8th, presentation of vertex, not engaged, in left transverse diameter, labour began on Oct. 19th, at 8 P.M., spontaneous rupture of membranes at 1 A.M. on the 20th, at morning visit on Oct. 20th M. Varnier reported that the head which presented in left transverse diameter, not engaged, an attitude midway between flexion and extension, was inclined on the anterior parietal region (obliquity of Naegele), foetus large, dilatation equal to a five-franc piece, progress impossible, considering the obliquity of Naegele, deflexion, the retraction of the pelvis and the position of the foetus. If these things did not correct themselves it would be useless and dangerous to apply the force. Symphysiotomy would have to be performed at once if the head did not become engaged of itself. At 5 P.M. dilatation was complete, at 10 P.M. manual exploration showed that the head had not moved a line, at 11.50 P.M. Wallich performed symphysiotomy, which resulted in immediate separation (at 12.10) by abduction of the thighs to 2.5 cm., a first application of the forceps having slipped (12.15) and there being a prolapse of the coccyx M Varnier made a second application rapidly in flexion, succeeded in extracting at 12.20 (during which the separation reached 4.5 cm.) a boy weighing 3650 grm (8 lb.), who, born apparently dead, but began to breathe at 12.27 and cried at 12.31, the cephalic diameters were: Occipito-mental 13.5 cm., occipito frontal, 12.3 cm., sub-occipito-bregmatic 10.4 cm., sub-occipito frontal, 11.4 cm., biparietal, 9.5 cm., bitemporal, 7.9 cm., circumference—sub-occipito bregmatic 33.0 cm., sub-occipito-frontal, 35.0 cm., this child, nourished by a wet-nurse, weighs now 4610 grm (over 10 lb.), puerperal condition temperature 38.6°C (101.3°F) during the first six and seventh days, union by first intention, still removed on Oct. 29th, the patient rose on Nov 8th (nineteenth day), she walked well and without pain. Nov 16th, on which day the temperature was 38.4°C (101.2°F), on the next day she had phlegmasia alba dolens of the left leg for which she is still being treated.

CASE 13 Nov 13th, 1892 (Potocki) —F—, aged thirty eight. The notes were as follows. Two confinements, pelvis rachitic, annular, promonto subpubic diameter 9.7 cm. First confinement in 1880, at term, cephalotripsy. Second confinement on Nov 13th, 1892 (Clinique Baudeloque), last monthly period from Feb. 1 to 22nd, 1892, breech presentation transformed by internal version into occipito iliac right transverse, labour began on Nov 11th at 11 P.M., spontaneous rupture of membranes occurred at midnight, dilatation was complete on Nov 13th at 8 A.M., considering the information furnished by palpation, M Potocki performed symphysiotomy at once (nine minutes), which was followed by spontaneous separation to 3 cm., at 9.11 A.M. the application of the forceps resulted in the extraction at 9.4 (during which the separation amounted to 5.7 cm.) of a boy weighing 3300 grm (over 7 lb.), born apparently dead,

chloric acid plays in primary gastric digestion, I am disposed to believe that at any rate one considerable group of anæmias originates in the initial failure of the albuminoids to undergo normal transformation through defect of gastric hydrochloric acid, thereby leading to blood impoverishment, not necessarily in consequence of the active destruction of corpuscles but from the failure to provide sufficient and proper material necessary for their construction. In order to test the correctness of this supposition I have selected a case of grave anæmia, associated with the complete absence of gastric free hydrochloric acid in the stomach, and which is at present under treatment by hydrochloric acid, as the only therapeutic remedy the patient receiving 100 minims daily of the dilute acid. The case is still under observation, but the results at this stage are sufficiently interesting and instructive to justify my proceeding with the trial.

CASE 1.—J I—aged seventeen, a shop girl was admitted to Ward 30 on May 19th 1892, suffering from chlorosis. There was no evident decrease in the number of red corpuscles which were about 5,000,000 per c.mm. The hæmoglobin was down to 40 per cent. The blood cells were smaller than normal and defective in form. It will be seen by reference

CASE 1

Corpuscles anemorphous.

to the chart that the corpuscles remain almost stationary at a comparatively high standard, and the hæmoglobin steadily rises to 85 per cent. This deviation from the usual course is characteristic of the chlorotic type of anæmia.

Treatment.—Sulphate of iron. The slow recovery of the hæmoglobin was peculiar to chlorosis and the treatment was prolonged to forty days.

Progress

Date.	R. d corpuscles	Hæmoglobin.
May 9 h	5,110 000 per c.mm.	40 per cent.
„ 28th	6,810 000 „	64 „
June 7th	5,240 000 „	70 „
„ 13th	5,780 000 „	80 „
„ 22nd	5,270 000 „	86 „

CASE 2.—J D—aged eighteen, was admitted to Ward 30 on Nov 21st suffering from symptomatic anæmia complicated with intercurrent influenza. The temperature on admission

CASE 2.

Duration of treatment twenty-six days.

was 105 F, the pulse 140 and the respiration 48. By means of antipyrin her temperature was reduced in twenty four

1 The dotted line in the charts represents the percentage of hæmoglobin in the blood at definite periods of the case and the continuous line the number of blood corpuscles per c.mm.

hours to normal. Nine days thereafter she was prescribed sulphate of iron for the anæmia, which persisted after convalescence from influenza. The blood at the commencement of treatment was reduced to 1 150 000 red corpuscles per c.mm. with only 20 per cent of hæmoglobin. At the end of twenty-six days the red cells numbered 5 800 000 per c.mm. and the hæmoglobin 68 per cent. The patient was discharged cured on Dec. 26th.

Treatment.—Sulphate of iron. The recovery of red corpuscles and hæmoglobin was equally progressive throughout, cure resulting in twenty six days.

Progress

Date	Red corpuscles.	Hæmoglobin.
Nov 30th	1 150 000 per c.mm.	20 per cent
Dec. 26th	5 800 000 „	68 „

CASE 3.—M D—, on admission to Ward 30 on Oct 28th, was suffering from symptomatic anæmia. Her red corpuscles were reduced to 1,590 000 per c.mm. and the hæmoglobin to 25 per cent. Sulphate of iron and liquor arsenicalis were at once prescribed. The effects were immediately apparent, and continued progressing until Nov 29th, when of her own accord, she left the hospital to resume her work in a factory. In ordinary circumstances she would not have left hospital

CASE 3.

for a couple of weeks longer by which time the red corpuscles would have been over 5 000 000 per c.mm. and the hæmoglobin would probably have registered 70 per cent. This case fairly shows the average time of recovery in symptomatic anæmia treated from the first with iron. It further shows the equal improvement in both constituents.

Treatment.—Arsenic. Doubtful as to any specific effect on the blood corpuscles or hæmoglobin. It manifestly does not retard, and probably enhances, the effects of the iron. Sulphate of iron. Its twofold effect upon the red corpuscles and hæmoglobin were at once apparent.

Progress

Date	Red corpuscles.	Hæmoglobin.
Oct 28th	1,590 000 per c.mm.	25 per cent
Nov 24th	3,240 000 „	31 „
„ 29th	4,210 000 „	60 „

CASE 4.—B. R—aged eighteen, was admitted to Ward 30 on Oct 24th 1892, suffering from typical chlorosis. On admission she was put on ordinary ward diet, to which

CASE 4

Corpuscles heteromorphous. Some abnormally large and some abnormally small.

were afterwards added maltine and port wine and this trial was continued over thirty six days. During that space the red blood cells had increased from 1 030 000 per c.mm. to

constant apposition—or in a “gouttière de Bonnet” This is possible in a hospital but might be impossible in ordinary practice, though I think that the simple apposition of the legs with a well applied trunk bandage very firm in the pelvic region, or a plaster bandage such as I had for my first case, would be quite sufficient. The superiority of my bed or of the “gouttière de Bonnet” consists in the facility with which the whole body can be raised without causing the least movement of the pelvis. The sutures should be removed on the eighth day and then the patients can turn in the bed easily and without pain. Although one of our cases rose without permission on the fourteenth day and no harm resulted, I think it prudent not to let the patients rise till about the twentieth day. This, in my opinion, is the best course to follow during and after the operation. The open section of the symphysis, from above downwards and from before backwards, which may be called the French method, is an operation which does not require any complicated array of instruments. A short-bladed bistoury, firm and fine, and a probe-pointed bistoury are absolutely sufficient, but I would recommend you to have as well a chain saw and a registering separator. The chain saw will be your ultimate resource if by chance you cannot cut the symphysis. It is said that sometimes the symphysis is ankylosed. That may be so, for I do not pretend to have seen everything, but all I can affirm is that I have made a section of the symphysis on the cadavers of more than 100 aged females and have never met with ankylosis. The self-registering separator will enable you to follow the progress of the separation during the extraction. In several of our cases we have seen separation go beyond 6 cm., and in these cases consolidation of the pelvis took place as well and as quickly as in the cases where the separation did not exceed 4 cm. I think it would be unwise to go beyond 7 cm., and it is necessary to increase the slowness of the extraction and to render the pelvis immobile when the needle begins to pass 6 cm. And if I insist on this point it is less from fear of producing lesions in the region of the sacro iliac synchondrosis than from a desire to avoid lesions of the soft parts in the region of the vulva, vagina and bladder. We have never observed lesions of the urethra or bladder, but in three cases (6, 9, and 11) we noticed after the extraction a small vestibulo vaginal rupture, communicating, in one case at least, with the operation wound. These lacerations healed quickly and without sutures, but similar solutions of continuity might be the starting point of lesions more extensive and deeper and on that account more serious.

2 *What place ought symphysiotomy to occupy among obstetrical operations?*—To day one can say not only that symphysiotomy is resuscitated, but that it ought to occupy a foremost place amongst obstetrical operations. It ought to occupy a foremost place, I say, because it is most essentially a conservative operation. It does not and should not injure any important organ of the mother. It can and should save the child from all grave lesions. Does this mean that statistics will never register a death either of mother or foetus? Certainly not. But will the operation be to blame in all these cases? Symphysiotomy will be practised in cases where the application of forceps has already been tried and in cases already infected. These cases may succumb. Would they only succumb after symphysiotomy? No, embryotomy and Cæsarean section would not have given a better result. I do not deceive myself. I shall be opposed and treated as an enthusiast, but meanwhile, till some one shows me a woman who has died solely from symphysiotomy, I shall persist in my conviction. I have had the pleasure of seeing my master (M. Tarnier) support symphysiotomy with his great authority. I have a not less sincere pleasure in seeing Professor Leopold, the great performer of Cæsarean sections, adopt and put in practice our method. I see that numbers of our colleagues and *confrères* think and act as we do. That is enough, I shall leave facts to convince or convert others.

3 *What are and what will be the influence of symphysiotomy on other obstetrical operations?*—On some it will be good and on others it will be very bad. Amongst the latter I cite first of all embryotomy practised on a living foetus. Its day is over, we are for ever rid of this nightmare. The Cæsarean operation, followed or not by the amputation of the uterus and ovaries, will become more and more rare. Indications for this will still be found in cases of uterine and other tumours filling the pelvic cavity, but happily such cases are not very numerous. Yet even in some of these cases symphysiotomy may be indicated. Thus M. Lepage, our

chef de clinique, has practised in this city, with success both as regards the mother and the child, a symphysiotomy in a case where a tumour partly obliterated the pelvis. In cases of contracted pelvis the Cæsarean operation ought only to be recognised in cases of absolute necessity. The cases of pelvis where this operation is positively indicated are so rare that it is most likely you will never meet with one. If the relations between symphysiotomy and embryotomy and the Cæsarean operation are easy to define, the task is not so easy when it is necessary to establish the relations between symphysiotomy on the one side and premature delivery and the application of forceps on the other. Still I think one can say from to day that symphysiotomy is calculated to render great service in cases of induced labour. It will at least prevent the induction of labour too prematurely. The fear of an obstacle from the contracted pelvic cavity will no longer haunt us, and knowing that we have the power of, and I might say the faculty for, enlarging the passage we can wait calmly for the maturing of the foetus so that its capability for extra uterine life may be certain. A point, which can only be decided by long experience and by a considerable number of well observed facts, is the following. Is it better to induce labour at eight months, counting on natural delivery, or to wait for the spontaneous onset of a tempestuous labour and then perform symphysiotomy? I do not feel at liberty to express my opinion on this subject yet. I have formed an opinion, but I must wait before making it known to see whether many observations will support or modify it. I symphysiotomy ought to bring to an end all labours induced too prematurely it ought also to make all forcible applications of forceps disappear. How often, in the fear of having to practise an embryotomy and in the hope of extracting a living child, have we not—have I not, I should say—exercised such long and strong traction that the result was nothing but a cephalotripsy in disguise? Symphysiotomy ought to put an end for ever to all such tractions. When a perfect application of the forceps has not been able to engage the head, after moderate tractions there is only one thing to be done, and that is, to withdraw the instrument and practise symphysiotomy as I did in my second case, where the pelvis was not rachitic and very little below the normal, but in which the foetus was extremely large.

You see, gentlemen, the influence already exercised by symphysiotomy on the majority of obstetrical operations. You see the beneficent part it exercises and will exercise in nearly all cases of pelvic contraction. In pelvis simply small or flattened, in pelvis contracted by rickets—that is, with the contraction at the pelvic entrance—and in pelvis contracted at the outlet, the latter gaining more from symphysiotomy than when the entrance is affected. There only remain the asymmetrical pelvis and especially the pelvis obliquely ovalar with synostosis of one sacro iliac symphysis. Here symphysiotomy loses half or all its advantages, it is true, but I am happy to tell you that I have been able to practise in a case of this kind with success an operation conceived and described by Professor Farabœuf—namely, ischio pubiotomy—which I performed for the first time on Nov 9th and which I may have the honour of relating to you in future lecture.

ON THE TREATMENT OF ANÆMIA AND CHLOROSIS BY THE CHIEF IRON PREPARATIONS COMMONLY IN USE

By ANDREW SMART, M.D., F.R.C.P. EDIN,
PHYSICIAN TO THE ROYAL INFIRMARY OF EDINBURGH ETC

THE patients whose cases are here reported were under my care in Wards 30¹, 32² and 33² during the past year (1891-2). The cases include symptomatic anæmia, chlorosis and pernicious anæmia, and the object chiefly contemplated was to satisfy myself as to the relative efficacy of some of the chief ferruginous substances employed in their treatment also, to ascertain whether our present views in regard to them are correctly founded, and, further, to decide its importance to be attached to the varying amounts of red corpuscles and hæmoglobin which characterise the course of those diseases. Recognising the important rôle which hydr

* Menstruation.

CASE 8.—J L.—aged seventeen was admitted to Ward 30 on July 18th, 1892, suffering from symptomatic anemia. She was put on diet only for the first nine days with the result that the hæmoglobin increased from 30 to 40 per cent., the corpuscles showing nearly the same enumeration—namely 2,000,000 per c.mm. On July 27th the patient was prescribed seven grains of iron, thrice daily afterwards the hæmoglobin

and red corpuscles progressively increased until Sept. 9th. At that date the corpuscles were 5,800,000 per c.mm. and the hæmoglobin 70 per cent. the patient having been forty three days taking phosphate of iron.

Treatment—Diet only Hæmoglobin moderately increased red corpuscles stationary Phosphate of iron Hæmoglobin and corpuscles progressively recovered, but recovery is slower than with some of the other irons

CASE 9.—M G.—aged nineteen was admitted to Ward 30 on Nov 4th 1891, suffering from symptomatic anemia. On admission the red corpuscles were 1,900,000 per c.mm. and the hæmoglobin 10 per cent. She was at once put on treatment by peroxide of iron which was continued for fifteen days. During this time the corpuscles were reduced to 1,640,000 per c.mm., but the hæmoglobin increased to 26 per cent. An examination six days later showed that the corpuscles had returned to their original number, but that the hæmoglobin had diminished to 20 per cent. The result of this trial with peroxide of iron proving unsatisfactory, it was suspended and the sulphate of iron substituted. After fifteen days during which the sulphate of iron was continued the corpuscles had risen to 2,250,000 per c.mm. and the

CASE 9

Corpuscles irregular

hæmoglobin to 38 per cent and seven days later the blood cells had increased to 4,630,000 per c.mm. and the hæmoglobin to 70 per cent. The actual time of treatment by sulphate of iron was twenty six days. The three weeks' trial with peroxide of iron is practically out of account

Treatment—Peroxide of iron Results negative. Sulphate of iron Normal restitution of corpuscles and hæmoglobin in twenty six days

Date	Red corpuscles.	Hæmoglobin.
Nov 6 h	1,900,000 per c.mm.	10 per cent.
24th	1,640,000	26
30th	1,900,000	20
Dec. 15th	2,250,000	38
26th	4,630,000	70

(To be concluded.)

5,830,000 per c mm., but the hæmoglobin had fallen from 38 per cent to 32 per cent., so that, as regards the hæmoglobin, the patient being on diet only, the whole of the trial had been retrograde. On Dec 1st perchloride of iron was prescribed and continued for fourteen days. At the end of that time the hæmoglobin had risen to 40 per cent., but the red corpuscles were reduced to 2,000,000. This remedy proving unsatisfactory, the sulphate of iron was substituted for it on Dec 14th, and from that date there followed immediate and progressive increase in both constituents. On Dec. 26th, when the patient left hospital, the red corpuscles were 4,720,000 per c mm., and the hæmoglobin 68 per cent.

Treatment—Diet (thirty six days) Increase of red corpuscles, diminution of hæmoglobin. Perchloride of iron (fourteen days) Increase of hæmoglobin, reduction of red corpuscles. Sulphate of iron (twelve days) Progressive increase in hæmoglobin and red corpuscles.

Progress

Date	Red corpuscles	Hæmoglobin
Oct. 24th	1,030,000 per c mm.	38 per cent
Nov. 7th	2,800,000 "	40 "
" 14th	3,800,000 "	32 "
" 29th	2,250,000 "	32 "
Dec. 14th	2,100,000 "	40 "
" 26th	4,720,000 "	68 "

CASE 5—K M—, aged twenty one, was admitted to Ward 30 on June 25th, 1892, suffering from symptomatic anæmia. Her condition represented a severe type of the symptomatic group, with 2,600,000 red corpuscles per c mm. and 25 per cent. of hæmoglobin. Both constituents remained stationary at the end of eight days on diet only. On July 3rd five minims of liquor arsenicalis were prescribed three times daily, the dose to be increased to thirty minims daily. An examination of the blood on July 10th showed the hæmoglobin to be stationary and the red corpuscles almost so. On July 11th sulphate of iron was substituted for the arsenic. From that date the hæmoglobin and red corpuscles markedly and rapidly increased to Aug. 16th, when the patient was discharged in perfect health, the red corpuscles being 6,400,000 per c mm. and the hæmoglobin 68 per cent. By comparison

oxide of iron, to be given thrice daily. It was ascertained on Aug 4th that the red corpuscles had increased to 3,800,000 per c mm. and the hæmoglobin to 46 per cent. Steady progress continued to be made until Aug 23rd, at which time the patient left the hospital cured. At that date the red corpuscles had increased to 6,000,000 per c mm. and the hæmoglobin to 70 per cent. She was twenty six days on peroxide of iron treatment.

Treatment—Diet alone. Marked reduction in red corpuscles

CASE 6

and in hæmoglobin. Peroxide of Iron. Immediate and marked increase in both constituents, with complete recovery in twenty six days.

Progress

Date	Red corpuscles	Hæmoglobin
July 17th	1,900,000 per c mm.	40 per cent.
" 27th	1,500,000 "	30 "
Aug 4th	3,800,000 "	46 "
" 10th	4,600,000 "	56 "
" 17th	5,600,000 "	62 "
" 23rd	5,800,000 "	62 "

* Diet only

CASE 5

with chlorosis the difference in this case of symptomatic anæmia is strikingly brought out in the much more rapid and concurrent progress in both hæmoglobin and red corpuscles.

Treatment—Diet. No improvement. Arsonic. Improvement doubtful. Sulphate of iron. Immediate and continued improvement in red corpuscles and hæmoglobin.

Progress

Date	Red corpuscles	Hæmoglobin
June 25th	2,600,000 per c mm.	25 per cent.
July 3rd	2,500,000 "	25 "
" 10th	2,900,000 "	25 "
" 19th	3,300,000 "	30 "
" 26th	4,200,000 "	52 "
Aug 4th	5,200,000 "	66 "
" 11th	5,400,000 "	65 "
" 16th	6,400,000 "	68 "

CASE 6—M C—, aged twenty, a waitress, was admitted to Ward 30 on July 19th, 1892. She was then suffering from advanced chlorosis. The red blood corpuscles were reduced to 1,900,000 per c mm. and the hæmoglobin was 40 per cent. During the first ten days, on diet only, the corpuscles increased to 1,500,000 per c mm. and the hæmoglobin to 30 per cent. On July 27th she was prescribed fifteen grains of per

CASE 7—I S—, aged twenty four, was admitted to Ward 30 on May 14th, 1892, labouring under marked chlorosis with 3,600,000 per c mm. of red corpuscles and 28 per cent. of hæmoglobin. She was in the first instance put on ordinary diet, with the addition of maltine and port wine which were continued for twelve days, at the end of which the red corpuscles had increased to 5,900,000 per c mm., but the hæmoglobin only at 38 per cent. Notwithstanding this relatively large increase in the corpuscles the patient did not show evidence of being in a really improved condition. This stage treatment by sulphate of iron was begun given seven grain doses thrice daily. The immediate effect of this was evident in a marked increase in the hæmoglobin, the cells also increasing in number. She continued under the same iron treatment until July 25th, at which time she was in the Infirmary in perfect health with the percentage of hæmoglobin at 80 and the corpuscles numbering 6,500,000 per c mm. The point of chief clinical interest to be noticed in this typical case of chlorosis is the comparatively slow rate of increase in the hæmoglobin and the rapid and excessive restoration of the red blood cells. I have found this feature characteristic of the whole of the chlorotic group, marking a difference whereby chlorosis may generally be distinguished from symptomatic anæmia. As indicating that chlorosis is

at the bottom of the tube, but the fluid remains clear All cultures have a powerful, musty odour

GENERAL REMARKS

Definition—Several writers seem to have confused Streptothrix and Cladothrix. Thus Macé in his account of what he calls "Cladothrix dichotoma," describes an undoubted streptothrix. But the distinction is simple enough Cohn's definitions were—Cladothrix very fine leptothrix filaments, colourless, not articulated, straight or wavy, with false branching Streptothrix very fine leptothrix filaments, colourless, non articulated, straight or slightly spiral, with true branching Besides these, they are further distinguished by the former possessing a sheath which the latter does not It is in fact the presence of a sheath in Cladothrix that accounts for the false branching, for it holds together filaments which without it would fall asunder

History—The first to discover the cladothrix was Cohn, who two years later described and figured it, together with another organism which von Græfe and afterwards Foerster had observed in the lacrymal canal, and which Cohn now names Streptothrix Foerster. Cienkowski next studied the cladothrix. In 1877 he stated that he had seen both true and false branching but as he makes no mention of Streptothrix it is probable that he has confounded the two Zopf in 1882 published an excellent description of Cladothrix, which was accompanied by several valuable plates, he, however, could not distinguish between the two varieties and says that they could not be separated. But he denies that he has ever seen true branching in any organism whatever, and therefore it is evident that he had never studied the streptothrix Winter, two years later, considered Streptothrix and Cladothrix as synonymous terms Macé in 1888 succeeded in cultivating an organism which he called Cladothrix dichotoma, but, as mentioned before, this was a true streptothrix and differed in several particulars from true Cladothrix dichotoma. The specific cause of cattle disease in Guadeloupe—farcin de bœuf—was described in 1889 by Nocard as a cladothrix, but subsequent investigation by Metchnikoff showed it was a streptothrix. Billel who has considered the cladothrix from every point of view, and has gone into it very exhaustively, has endeavoured to cultivate this organism on ordinary media, but not altogether with success But in the hanging drop he has observed all the stages of development of the cladothrix, including the formation of rods and coccus forms Since 1890 Russell cultivated a true cladothrix from sea water, and Eppinger from a case of meningitis, has isolated a streptothrix, although he calls it a cladothrix, other forms of streptothrix have been isolated by Gasperini, Almqvist, Dorn, Gruber Sauvageau and Radais and lastly by myself

Reproduction—The methods by which reproduction is provided for in the different species are various In Cladothrix dichotoma Billel claims to have observed the formation of true endogenous spores The first stage in their formation is a retraction of the protoplasm of the filaments into a rectangular bacillus-like body, which then divides into two portions, each of which again similarly divides, so that we have the appearance of fine angular or rounded bodies (spores) enclosed within a clear hyaline sheath. In my cladothrix no spores could be observed. Macé says the filaments of Cladothrix dichotoma (sic) may become segmented into very short rods or spherical bodies which may be considered as arthrospores Dorn, according to Sauvageau describes sporiferous filaments which are very much thicker than the vegetative filaments and segment into spores These swell up by a process but little known, though certainly connected with the presence of air in the interior and rupture of the investing membrane sets the spores at liberty The method of sporulation described by Sauvageau and Radais in Oöspora Guignardi is very similar to that of Dorn and of my Streptothrix C The surface of all cultures on solid media is covered with a white powder, which consists of short sponiferous filaments, distinguished from the ordinary vegetative filaments by their much greater thickness Segmentation takes place simultaneously along the whole filament. The spores are round or oval and can easily be separated from each other They stain easily with aniline dyes and with Gram's stain. Almqvist describes a very curious method of fructification When cultivated in a thin layer of fluid the plant gives rise to filaments which rise out of the fluid into the air and there become segmented into oidiospores These spores become covered with oil produced by the plant itself so as not to be wetted, and can then be distributed by the wind to other places for development.

Place in classification—Cohn considered—and his opinion has been closely followed by Zopf and others—that Streptothrix and Cladothrix were closely allied Sauvageau and Radais on the other hand, think these two plants have nothing in common. They regard Cladothrix as a bacterium and Streptothrix as a mycelium, the latter, therefore, should be placed amongst the mould fungi and not amongst the bacteria. As regards Streptothrix, Dorn believes they belong neither to the bacteria nor to the moulds, but to a special group of their own Almqvist agrees with Cohn and Brefeld that Streptothrix is a bacterium and forms a connecting link with the Hyphomycetes I rather incline towards Sauvageau's view that Streptothrix and Cladothrix are not at all closely allied. The latter, I think there can be no doubt, belongs to the group of Bacteria, but the proper place for Streptothrix is by no means so readily determined. In certain characters—for example, the appearance of so-called coccus forms and short rods—they resemble the bacteria, other characters, however, such as the musty odour which most of them possess, and especially their fructification by means of conidia, point very conclusively to the Hyphomycetes They undoubtedly form a connecting link between the two families but I think, should be placed rather among the latter than the former

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI De Sed. et Caus. Morb., lib. iv Proœclum.

ROYAL FREE HOSPITAL

PNEUMONIA FOLLOWED BY ULCERATIVE ENDOCARDITIS
AND MENINGITIS.

(Under the care of Dr SAINSBURY)

CASES of malignant endocarditis though not very in frequent, are always interesting, and in particular in their etiology The present case illustrates the well known but ill-understood relation between pneumonia and this form of endocarditis According to Osler pneumonia was present in 11 out of 23 cases observed in Montreal and in 54 out of the 209 cases which he analysed in his Gulstonian Lecture. Meningitis is a not infrequent further complication, it was observed in 25 of the 209 cases, and in 15 of these 25 there was also pneumonia For the notes of this case we are indebted to Mr Wilmot H Evans B Sc. Lond., registrar

A furniture porter was admitted into the Royal Free Hospital on Nov 11th, 1892, under the care of Dr Sainsbury complaining of pain in the side and shortness of breath. In his family history there was nothing noteworthy He had lived in London for the greater part of his life, well clothed

ON THE GENERA STREPTOTHRIX AND CLADOTHRIX OF COHN

By G. W. DAMMAN, M.B., CH. B. MELB.

ASSISTANT BACTERIOLOGIST TO PROFESSOR RAY LANKESTER, OXFORD UNIVERSITY

WITHIN the last year or two several observers on the Continent have isolated and described a species of micro-organism consisting of branched mycelium like threads, and therefore not belonging to the Schizomycetes. So far as I am aware no one has described anything similar in this country, and therefore I make a few remarks about these plants and bring before the readers of THE LANCET the results of my own observations. But before entering into general considerations I shall first describe three members of this group which I have isolated and cultivated, one being chromogenic and the others colourless.

STREPTOTHRIX A

This organism was isolated on four occasions from unfiltered Thames water and closely resembles the oöspora Metchnikow of Sauvageau and Radau, also a plant described by Macé, which he erroneously considers identical with Cladotrix dichotoma of Cohn.

Morphology—The cultures are so firm and adherent that cover glass preparations are difficult to make. Preparations show fine filaments, with branches ramifying in all directions. There is no regularity in the branches, which are more numerous in some filaments than in others, or in different parts of the same filament. They arise as a small lateral bud at right angles to the axial stem but may rapidly incline at an angle to the mother stem and become more or less wavy or curled. The threads vary somewhat in thickness, Sauvageau and Radau explain this as being due to two threads running side by side for some distance. This explains the appearance in some cases, but in others it is certainly due to difference in thickness of the filaments themselves. This is all that can be seen of their structure when stained by gentian violet or fuchsine, but if stained by methylene blue, or still better by Gram's method, it is at once seen that the filaments are not homogeneous, they are irregularly broken up into stained and unstained portions, so as to resemble streptothrix forms, long and short rods, and coccus forms. This appearance is seen also in the fresh state and in cultures of all ages. This is undoubtedly what Cohn and Zopf have described as segmentation into micrococci, bacilli, streptothrix and spirilla. But they never become free, and in my opinion are due simply to an irregular distribution of the protoplasm, because I have seen all stages of their formation, from scarcely perceptible granularity to the most perfect chains of bacilli.

Biology—The organism appears on gelatine plates in two or three days as yellowish white points, gradually increasing in size and forming a fairly prominent button like colony with a matt surface and rounded outline. The gelatine surrounding the colony assumes a brown colour to the extent of about two millimetres, afterwards darkening almost to black. Under the microscope the colony appears as a dark brown mass, opaque in the centre, the margins consist of a confused network of threads, which is rather looser at the periphery. In about a week it forms a brownish white, tough, coherent skin slightly sunken owing to liquefaction of the gelatine, and the skin can be removed *en masse*. In puncture cultivations there is a brownish white growth on the surface, which may afterwards become somewhat wrinkled, but which never reaches the walls of the tube. Along the needle track there are a few indistinctly contoured colonies in the upper part, which with a lens are frequently seen to have a radial arrangement. The gelatine is stained brown, but the colour never extends to any depth in the gelatine. Liquefaction begins in about a week, but is slow and incomplete. On agar agar it forms discrete brownish white colonies which also produce the dark discolouration of the medium to which the culture is very firmly adherent. The condensation fluid is stained brown. In nutrient bouillon kept in the incubator at 35°C it grows very slowly, forming isolated colonies which do not render the fluid cloudy. These colonies consist of small rounded flakes which collect at the bottom of the culture tube. When one of these flakes is transferred to a slide it is seen to consist of a dense mass of filaments, which can only be distinguished at the periphery. The whole fluid is stained a deep brown.

CLADOTHRIX B

This was also obtained from Thames water, and presents several marked differences from the preceding variety.

Morphology—In gelatine cultures we see long filaments which may consist of two or more relatively shorter threads and may show remarkable tortuosity. As preparations are more easily made than in the case of the preceding organism the branches are very distinctly seen, and close observation shows that the branching is pseudo-dichotomous. The branches start as lateral buds, which are not necessarily at right angles to the parent stem and may exceed the latter in length. In many preparations a colourless sheath, about four times as wide as the protoplasmic portion, may be demonstrated, but it remains unaffected by any of the ordinary stains. As in Streptothrix A, methylene blue or Gram's stain show the so called segmentation very distinctly. But in agar and bouillon cultures, especially if young filaments consist of large sausage-shaped bacilli stuck together and connected by a colourless sheath. The filaments are not of uniform width and the extremities may present club-shaped swellings. In some places the unstained portion of the filament is seen to be much wider than at others and there may be a series of these swellings separated by intervening contractions which are deeply stained. Therefore I take to be simple dilatations of the sheath.

Biology—The organism grows fairly rapidly in gelatine plate cultivations. About the fourth day the plate is dotted with white rounded, coherent colonies which have an uneven surface and under the microscope appear dark and opaque. Two days later the margin is seen to consist of a meshwork of threads. In puncture cultivations a grey wrinkled layer seen on the surface, which during the next few days becomes more flattened and sometimes shows concentric rings. There is luxuriant growth along the puncture in the form of a white streak. Liquefaction begins in five or six days and extends gradually downwards, the liquefied gelatin being turbid and opaque. On agar agar there is rapid development of a broad grey shining band, the margins of which show transverse striation. Potato cultures are peculiar. At first there is rapid and abundant development of a shaggy raised, colourless sometimes opalescent growth, which in the course of a few days becomes covered with a pasty skin; afterwards subsides to the bottom of the tube. Bouillon remains clear, but a few fine flakes are deposited at the bottom, consisting of chains of large bacilli bent on to each other at an angle.

STREPTOTHRIX C

This organism was isolated from the saliva of a healthy individual. Its morphology is similar in every respect to that of Streptothrix A, but in addition there are certain threads which correspond to Comidia, they are usually short and thick and occasionally branched. The process of segmentation is thus. The filament swells somewhat and becomes slightly granular, the contour then becomes sinuous, there is an appearance of segmentation into coccus like bodies or spores. After this there is apparently no change for two or three days, and then suddenly the spores become liberated. They may be quite round, but are usually rather longer in one diameter. I have not observed the development of these spores into fresh filaments, but have no doubt that under suitable conditions this would take place.

Biology—In plate cultivations growth is slow. In four days we see a small round, shiny white colony, not raised above the surface. Under the microscope it appears dark brown, and later a thick felted arrangement of threads is seen at the periphery. In stroke cultures there is a grey ribbon like band with smooth edges, very shortly a white chalky streak appears in the centre of the culture, which increases with the development of the organism but always leaves a narrow margin of grey. This chalky portion is at first firmly adherent to the subjacent medium, but about the fifth day it can be removed as a white powder and is found to consist exclusively of oidia and oidiospores. Liquefaction begins about the same time and advances rapidly. Stab cultures are grey, with an irregular and pitted surface, and in the centre there is the same white chalky appearance. Along the puncture there is a good development of numerous closely arranged but isolated colonies. Agar agar cultures kept in the incubator at 37°C consist of isolated grey plaques much raised at the edges and depressed in the centre. At this temperature no spores are formed, but if kept at the ordinary temperature the white chalky appearance is quickly developed. In bouillon cultures there are some flaky masses

CHISLEHURST, SIDCUP AND CRAY VALLEY
COTTAGE HOSPITALA CASE OF FRACTURE WITH DISLOCATION IN THE
CERVICAL REGION, NECROPSY

(Under the care of Dr G W DAVIS)

THE following is an interesting account of a case of damage to the spinal cord in the cervical region, with fracture and displacement of parts of the fourth, fifth and six cervical vertebrae. It is probable that the cord was completely crushed by the injury, for from the first the deep reflexes were absent, and it is the absence of these which indicates the extent of the injury. There can be no doubt that the decision not to operate in the case of this patient was the correct one. The statistics of operation for paraplegia dependent on injury to the cervical spine are decidedly against any interference, especially in recent cases.

W G H— a sawyer aged twenty-one, was in a boat-swing on May 7th, 1892, with a companion. The swing was descending, and W G H— in the higher seat, let go the propelling rope to save his hat. In the act of leaning over the side to again secure the rope he was struck on the forehead by the first of the swing shores, this blow threw him across the swing, which then carried him to the further support, by which he was hurled to the ground, alighting on his head. The accident happened at 2.30 P.M. He was unconscious for an hour, his nose bled. He was thought to be drunk by the bystanders and was carried twenty feet and laid on the grass. A medical man who was present had him conveyed to the hospital. Dr. Davis was sent for at 5 P.M. and saw him at 5.20 P.M., about three hours after the accident. On admission the man was found to be very muscular and heavily built, with fair complexion. He was very collapsed but conscious. The pulse was heaving and slow (48), the head and face were markedly cyanosed, the smell, taste and hearing were good, the tongue could be protruded straightly, deglutition was good, the pupils were equal, they were contracted and did not react to light. No lesion was discovered on the head, except the bruise over the right frontal protuberance, there was partial abduction of the arms which were externally rotated, and the forearms and wrists were so flexed that the fingers touched the upper part of the deltoid on the same side, this position of the arms was involuntary. There was impairment of sensation throughout both upper extremities, localisation of feeling was most marked over the region of the deltoid. There was much pain over the lower cervical region, over the right scapular region, and down the right arm, there was a feeling as of a weight on the right arm and the patient continually reiterated his request that the weight might be removed, there was complete motor and sensory paralysis from and below a line drawn on a level with the lower border of the second costal cartilage, bordering and above this line was a hyperæsthetic zone of about one inch in breadth, but extending so far as it was possible to test, all around the body. The skin reflexes were absent, with the exception of the plantar reflex, slight stimulation elicited no response, but if the finger nail was drawn sharply and firmly across the sole of the foot the great toe was, after a distinct interval momentarily abducted to the extent of about one eighth of an inch. The conjunctival reflex was normal. The knee-jerk and ankle-clonus were not obtainable. Fæces had been passed involuntarily between the time of accident and admission. There was partial priapism. His temperature was 96°. Four ounces of dark coloured urine were drawn off and found to contain a trace of albumen. The respiration was altogether diaphragmatic. At 11 P.M. some vomiting occurred, besides much food stuff, which contained a teaspoonful of blood clot. The patient asked frequently to have his head raised—that is, that the head might be so extended as to tilt the chin and arch the neck. A cervical cushion, as suggested by Hilton, was tried, but could not be endured.

May 8th.—The shock seemed to have passed off. Cyanosis was much less marked. The zone of hyperæsthesia was not so well defined. Pain was complained of in the abdomen when the urine was drawn off. The urine was normal. Bullæ had developed over the phalangeal end of the left index metacarpal and over the inner side of the left gastrocnemius. Towards evening he said "The pain at the right arm is better and comes and goes, but the pain in the neck keeps jumping." Temperature at 8 A.M. 100°, at 8 P.M. 98.4°.

8th.—An enema of gruel and oil was administered without effect until followed by gentle massage over the course of the

colon. Towards evening the susceptibility to noises increased. Temperature at 8 A.M. 99° F, at 8 P.M. 98.4° F.

10th.—Since the previous night he had been wandering at times. The sensitiveness to sound was increased, the discomfort and pain in the neck were such that no position of the head was bearable, an icebag was applied to the head, an enema followed by massage led to a motion of the bowels. Temperature at 8 A.M. 97.4° F, at 8 P.M. 99° F.

11th.—Deep pressure over the trunk was distinctly felt, but could not be localised, he asked for the bedpan, but passed nothing but flatus, as on all previous days. A consultation of the medical officers of the hospital was held with a view to decide as to whether it would be desirable to interfere either by extension or by operation, or to place the patient in a fixed apparatus and it was decided that it would be rather to the patient's interest to follow an expectant line of treatment, placing him in a fixed apparatus. Temperature at 8 A.M. 99° F, at 8 P.M. 101° F.

12th.—A cushion under the neck was now well borne. There was a feeling over the trunk as of the pattering of mice running over it. There was some redness of the right elbow. Temperature at 8 A.M. 96.4°, at 8 P.M. 101°.

13th.—Towards the evening he complained of being 'short of wind,' and occasionally moved the muscles of the neck in laboured inspiration. Slight cyanosis was present about the lips and the ears. Temperature at midday, 100.2°, at 8 P.M. 102°.

14th.—Inspiration was laboured all day, the difficulty increasing as the day advanced, accompanied by a perpetual nodding of the head from the traction of the neck muscles at each inspiration. To the rhythm of this nodding he imagined that he heard the ringing of church bells (he was one of the ringers of the church bells in his parish). Several times in his delirium he threatened to commit suicide. Temperature at 8 A.M. 98°, at 8 P.M. 96°. There was some difficulty in swallowing late in the evening.

15th.—Died quietly at 2.30 A.M.

Necropsy—Rigor mortis was well marked, there was much post mortem hypostasis. Palpation with care over each separate spinous process failed to discover the site of the lesion. On reflecting the muscular flaps from the neural arches infiltration with extravasation into tissues hardened by coagulated inflammatory exudation was remarked opposite the left lamina of the fifth cervical vertebra, which was seen to be fractured about its centre in such a manner as to leave a gap of a quarter of an inch on the left side of the fifth arch. The neural arches of all the vertebrae were uncovered, but no further fracture was found, and the vertebrae from the atlas to the sixth cervical were removed for further examination. On reflection of the scalp a large discoloured patch was found just behind the right parietal eminence. On removal of the vertex the dura mater was found glued to the bone opposite the site of the bruised scalp and also at the corresponding part on the inner surface of the cerebrum, the medium of connexion being fresh lymph. The brain itself appeared to be healthy but there was some fluid of a carmine tinge in the lateral ventricles. Further examination of the removed vertebrae showed the following. A longitudinal conjugate section through the vertebrae and included cord showed that the spinal canal was diminished by two-thirds of its extent through the projection backwards of the body of the fifth cervical vertebra, which was wedge shaped and detached from the anterior common ligament. The cord opposite the site of pressure was greatly diminished in bulk and diffident. Examination of the dry bones disclosed the following fractures—Fourth vertebra fracture of the right transverse process. Fifth vertebra fracture of the left lamina and crushing and starting of the vertebral body. Sixth vertebra: fracture of the projecting lip on the superior surface of the vertebral body on the left side, detachment of the superior posterior edge of the body. No visceral lesion was discovered. The remainder of the spinal canal was not opened for lack of time.

Remarks by Dr DAVIS.—Most of the symptoms in the case above reported have already been accounted for and their significance recognised. The contraction of the pupils in lesions above the second dorsal nerves, the fall of blood pressure from disconnection of the vaso-motor nerves from the higher centres, the position of the arms in lesions involving the sixth cervical nerves. Every case may, however, be the means of bringing about a more exact knowledge of some one or more particular symptoms. The case reported would seem to assist in the elucidation of three points. 1. Although

and well fed, but he frequently got wet through, and his hours of work were very long. He had never taken more than a moderate amount of alcohol until about a fortnight previously, but since then he had taken much rum. He had rheumatic fever at the age of twenty one and had had winter cough for many years. Seven days before admission he got wet through early in the morning and kept his wet clothes on all day. Two days later he awoke complaining of great pain in the abdomen, and though he got up the pain increased so much that he had to return to bed. During the day he shivered several times, but had no distinct rigor, there was also some diarrhoea. That night he was in much pain and was unable to sleep, and with every breath he felt a sharp stabbing pain in the right side, and his cough (which he had had about two months) became more troublesome. The next morning he consulted a medical man. He was told that he had pleurisy and that he should go to bed. A poultice was applied to the side. That night he was very restless and was slightly delirious. The next two days he continued in much the same condition, but his cough grew worse, the amount of sputum increased and some of it was said to have been black. Each evening delirium came on and he could not sleep. On the 10th he was delirious, got out of bed and walked down stairs. When the medical man saw him, he said the patient had "inflammation of the lungs" and advised his friends to take him to a hospital, the next day he was admitted to the Royal Free Hospital.

Nov 11th.—The patient lies on his back in bed, though he can lie on the side. His face is somewhat cyanosed. Temperature 100.6°, pulse 100, respiration 38. He complains of pain, stabbing in character, in the right side, much worse on breathing deeply. He has a cough, which is not severe, the sputum is viscid and in parts it is "rusty". The respiration is short and shallow. On percussion the note on the left side is normal, on the right in front it is resonant also, but in the axilla and behind there is dulness. On auscultation expiration is slightly prolonged all over the chest, due to the emphysema present, in the right axilla the breath sounds are weak and at the back on the right side there is well marked bronchial breathing, best heard to the inner side of the angle of the scapula, and here there is well marked pectoriloquy. No adventitious sounds are to be heard. Vocal resonance is diminished in the right axilla, but is increased at the back on the right side. The heart's apex beat is in the fifth space in the nipple line, but is very indistinctly felt. The heart sounds are normal but faint. The appetite is poor, there is much thirst, the tongue is coated with white fur. The urine has a specific gravity of 1018 and contains no albumen. He was put on a milk diet and five grains of carbonate of ammonium were prescribed every four hours.

12th.—He has had a fairly good night, though delirious at times. He tries to get out of bed, but answers fairly well questions put to him.

14th.—He continues in the same condition with much delirium and but little sleep. In the right axilla the breath sounds are bronchial and there is increased vocal resonance. Behind at the right base some fine crepitations can be heard. The temperature has fallen to normal.

16th.—Condition practically unchanged. Crepitations are heard in the right axilla. The expectoration has increased and the sputum is more markedly "rusty".

18th.—He sleeps better, but complains of his feet feeling cold. The cough is much better and there is no "rusty" sputum. The delirium has gone.

23rd.—The bronchial breathing has entirely disappeared, but there is some dulness at the right base.

26th.—At six o'clock this morning the temperature rose to 101.4°. He complains of a sharp pain in the left axilla, but no physical signs can be discovered. He has had slight shivering this morning. In the evening the temperature fell about a degree.

27th.—He had a rigor about noon, and the temperature rose to 103.4°, but fell rapidly to 98, with profuse sweating. He felt a severe pain in the left axilla.

28th and 29th.—On each day he felt a chill, and the temperature rose to over 103° falling again rapidly. No abnormal physical signs can be detected in the chest. He was delirious at night.

30th.—At mid day he had a rigor, the temperature rising to 102°. He was ordered five grains of quinine every six hours. The sputum was examined for tubercle bacilli, but none were found.

Dec 1st.—The temperature is 103.2°, no abnormal signs

can be discovered in the lungs. The first heart sound has a blowing character at the base. In the afternoon he became very drowsy, and his breath was very offensive. Exploratory needles were inserted behind in the seventh and eighth spaces, and a little bloodstained fluid was withdrawn. The temperature has risen to 105.4°.

3rd.—He is very drowsy. The tongue is dry and brown, but the breath is less offensive. The legs and arms are cold and bluish. The pupils are unequal. There is external strabismus. No optic neuritis. A double blowing murmur can be heard at the base of the heart. He sank gradually. During the day the temperature rose until it was over 106°. In the night he had clonic spasms of the arms and legs, and died.

Necropsy performed by Dr ANDREWES.—Brain. In the subarachnoid space there was much exudation of semi-purulent lymph with excess of fluid. The meningitis was well marked on the convexity, but was still more marked at the base of the brain. There was no actual pus. The brain itself was healthy. Heart. On that segment of the aortic valve which lies opposite the right coronary artery there was a mass of greenish vegetation, soft and friable. It was as large as a small hazel nut and into it projected a small aneurysm of the valve. The two other cusps of the valve were healthy. The aorta showed slight fatty degeneration of the intima and had not been infected by the vegetation. Lungs. Both were very congested and oedematous. On the surface of the lower lobe of the left lung there was a small whitish patch, which was sharply outlined. The lower lobe of the right lung had nearly recovered from the pneumonia but close to the base, in the centre of the lobe, there was a small cavity (about three-quarters of an inch in diameter) full of pus, apparently sweet. On the right side there were dense, pleural adhesions, but there were none on the left. The other organs were healthy.

We are also indebted to Dr Andrewes for this further note with regard to the microscopical and bacteriological examination of some of the parts removed. "Cover glass preparations made from the aortic vegetation showed numerous organisms all of one kind—viz., short bacilli, with bipolar staining, often arranged end to end or even in short chains. At first it was thought that there might be diplococcus pneumoniae, but it was not possible to demonstrate any very distinct capsule, and on the whole they appeared to be short bacilli rather than diplococci. Sections of the vegetation showed these same organisms, arranged in sharply defined masses, here and there throughout its thickness. Numerous cultivations made from a fragment of the fresh vegetation both on gelatin and on agar agar, remained perfectly sterile, not a single colony grew. The growth of the organism under aerobic conditions was not tested. The meningeal exudate contained numerous pus cells and a few micro-organisms of various sorts. Cultivations yielded various species, including staphylococcus pyogenes aureus. No one organism predominated, and no satisfactory conclusion could be drawn."

Remarks by Dr SAINSBURY.—The patient was admitted on the seventh or eighth day of the disease, on the eleventh day the temperature became normal and on the fourteenth day the disease appeared to have departed. After an interval of seven or eight days there occurred a sudden rise of temperature and thence onwards till death seven days later an irregular pyrexia was maintained. The delirium reappeared with the return of fever and the disease assumed a typhoid character. A probable diagnosis of malignant endocarditis was made which was enforced by the discovery of the double bruit at the base, but it must be confessed this bruit was very feeble. The case, it has been remarked, shows in its etiology a sequence of events frequently witnessed—viz., lobar pneumonia—malignant endocarditis also in the further occurrence of meningeal trouble it is not unusual, but I would point to the presence of a small abscess in the centre of the pulmonary lobe as a rare event in pneumonia. I would also draw attention to the occurrence of one attack of rheumatic fever at the age of twenty one, which, though the lesions of the aortic valve appeared at the necropsy to be wholly recent, may possibly have caused slight mischief to this valve, the subsequent and fatal endocarditis being grafted upon a slight damage of this kind. This is supposition only, but the precedence of an illness with marked endocardial affinities should not be overlooked, and it is clear that an acute inflammation such as was here found might obliterate all evidence of an old standing inflammatory residuum.

CHISLEHURST, SIDCUP AND CRAY VALLEY
COTTAGE HOSPITALA CASE OF FRACTURE WITH DISLOCATION IN THE
CERVICAL REGION, NECROPSY

(Under the care of Dr G W DAVIS)

THE following is an interesting account of a case of damage to the spinal cord in the cervical region, with fracture and displacement of parts of the fourth, fifth and six cervical vertebra. It is probable that the cord was completely crushed by the injury, for from the first the deep reflexes were absent, and it is the absence of these which indicates the extent of the injury. There can be no doubt that the decision not to operate in the case of this patient was the correct one. The statistics of operation for paraplegia dependent on injury to the cervical spine are decidedly against any interference, especially in recent cases.

W G H— a swayer aged twenty one, was in a boat-swing on May 7th, 1892, with a companion. The swing was descending, and W G H—, in the higher seat, let go the propelling rope to save his hat. In the act of leaning over the side to again secure the rope he was struck on the forehead by the first of the swing shores, this blow threw him across the swing, which then carried him to the further support, by which he was hurled to the ground, alighting on his head. The accident happened at 2.30 P.M. He was unconscious for an hour, his nose bled. He was thought to be drunk by the bystanders and was carried twenty feet and laid on the grass. A medical man who was present had him conveyed to the hospital. Dr Davis was sent for at 5 P.M. and saw him at 5.20 P.M., about three hours after the accident. On admission the man was found to be very muscular and heavily built, with fair complexion. He was very collapsed but conscious. The pulse was heaving and slow (48), the head and face were markedly cyanosed, the smell, taste and hearing were good, the tongue could be protruded straightly, deglutition was good, the pupils were equal, they were contracted and did not react to light. No lesion was discovered on the head, except the bruise over the right frontal protuberance, there was partial abduction of the arms, which were externally rotated, and the forearms and wrists were so flexed that the fingers touched the upper part of the deltoid on the same side, this position of the arms was involuntary. There was impairment of sensation throughout both upper extremities, localisation of feeling was most marked over the region of the deltoid. There was much pain over the lower cervical region, over the right scapular region, and down the right arm, there was a feeling as of a weight on the right arm and the patient continually reiterated his request that the weight might be removed, there was complete motor and sensory paralysis from and below a line drawn on a level with the lower border of the second costal cartilage, bordering and above this line was a hyperæsthetic zone of about one inch in breadth but extending so far as it was possible to test, all around the body. The skin reflexes were absent, with the exception of the plantar reflex, slight stimulation elicited no response but if the finger nail was drawn sharply and firmly across the sole of the foot the great toe was after a distinct interval momentarily abducted to the extent of about one eighth of an inch. The conjunctival reflex was normal. The knee-jerk and ankle-clonus were not obtainable. Fæces had been passed involuntarily between the time of accident and admission. There was partial priapism. His temperature was 96°. Four ounces of dark coloured urine were drawn off and found to contain a trace of albumen. The respiration was altogether diaphragmatic. At 11 P.M. some vomiting occurred, besides much food stuff, which contained a teaspoonful of blood clot. The patient asked frequently to have his head raised—that is, that the head might be so extended as to tilt the chin and arch the neck. A cervical cushion, as suggested by Hilton, was tried, but could not be endured.

May 8th.—The shock seemed to have passed off. Cyanosis was much less marked. The zone of hyperæsthesia was not so well defined. Pain was complained of in the abdomen when the urine was drawn off. The urine was normal. Bullæ had developed over the phalangeal end of the left index metacarpal and over the inner side of the left gastrocnemius. Towards evening he said, "The pain at the right arm is better and comes and goes, but the pain in the neck keeps jumping." Temperature at 8 A.M., 100°, at 8 P.M. 98.4°.

9th.—An enema of gruel and oil was administered without effect until followed by gentle massage over the course of the

colon. Towards evening the susceptibility to noises increased. Temperature at 8 A.M., 99° F., at 8 P.M., 98.4° F.

10th.—Since the previous night he had been wandering at times. The sensitiveness to sound was increased, the discomfort and pain in the neck were such that no position of the head was bearable, an icebag was applied to the head, an enema followed by massage led to a motion of the bowels. Temperature at 8 A.M., 97.4° F., at 8 P.M., 99° F.

11th.—Deep pressure over the trunk was distinctly felt, but could not be localised, he asked for the bedpan, but passed nothing but flatus, as on all previous days. A consultation of the medical officers of the hospital was held with a view to decide as to whether it would be desirable to interfere either by extension or by operation, or to place the patient in a fixed apparatus, and it was decided that it would be rather to the patient's interest to follow an expectant line of treatment, placing him in a fixed apparatus. Temperature at 8 A.M., 99° F., at 8 P.M., 101° F.

12th.—A cushion under the neck was now well borne. There was a feeling over the trunk as of the pattering of mice running over it. There was some redness of the right elbow. Temperature at 8 A.M., 96.4°, at 8 P.M., 101°.

13th.—Towards the evening he complained of being 'short of wind,' and occasionally moved the muscles of the neck in laboured inspiration. Slight cyanosis was present about the lips and the ears. Temperature at midday, 100.2°, at 8 P.M. 102.

14th.—Inspiration was laboured all day, the difficulty increasing as the day advanced, accompanied by a perpetual nodding of the head from the traction of the neck muscles at each inspiration. To the rhythm of this nodding he imagined that he heard the ringing of church bells (he was one of the ringers of the church bells in his parish). Several times in his delirium he threatened to commit suicide. Temperature at 8 A.M., 98°, at 8 P.M., 96°. There was some difficulty in swallowing late in the evening.

15th.—Died quietly at 2.30 A.M.

Necropsy—Rigor mortis was well marked, there was much post mortem hypostasis. Palpation with care over each separate spinous process failed to discover the site of the lesion. On reflecting the muscular flaps from the neural arches infiltration with extravasation into tissues hardened by coagulated inflammatory exudation was remarked opposite the left lamina of the fifth cervical vertebra which was seen to be fractured about its centre in such a manner as to leave a grip of a quarter of an inch on the left side of the fifth arch. The neural arches of all the vertebrae were uncovered, but no further fracture was found, and the vertebrae from the atlas to the sixth cervical were removed for further examination. On reflection of the scalp a large discoloured patch was found just behind the right parietal eminence. On removal of the vertex the dura mater was found glued to the bone opposite the site of the bruised scalp and also at the corresponding part on the inner surface of the cerebrum, the medium of connexion being fresh lymph. The brain itself appeared to be healthy but there was some fluid of a carmine tinge in the lateral ventricles. Further examination of the removed vertebrae showed the following: A longitudinal conjugate section through the vertebrae and included cord showed that the spinal canal was diminished by two thirds of its extent through the projection backwards of the body of the fifth cervical vertebra, which was wedge shaped and detached from the anterior common ligament. The cord opposite the site of pressure was greatly diminished in bulk and diffident. Examination of the dry bones disclosed the following fractures—Fourth vertebra fracture of the right transverse process. Fifth vertebra fracture of the left lamina and crushing and starring of the vertebral body. Sixth vertebra—fracture of the projecting lip on the superior surface of the vertebral body on the left side, detachment of the superior posterior edge of the body. No visceral lesion was discovered. The remainder of the spinal canal was not opened for lack of time.

Remarks by Dr DAVIS—Most of the symptoms in the case above reported have already been accounted for and their significance recognised. The contraction of the pupils in lesions above the second dorsal nerves, the fall of blood pressure from disconnection of the vaso-motor nerves from the higher centres, the position of the arms in lesions involving the sixth cervical nerves. Every case may, however, be the means of bringing about a more exact knowledge of some one or more particular symptoms. The case reported would seem to assist in the elucidation of three points. 1. Although

the deep reflexes and most of the skin reflexes are lost in complete transverse lesions of the cervical cord, yet that the plantar reflexes may and often do persist is shown by the case just narrated, and by two cases in St Thomas's Hospital Reports, vol xx., in one of which the cord was actually divided. The remaining points I would put as questions 2 Would not the retention of urine occurring in these cases be perfectly well accounted for if it were understood that the proper muscles of the bladder were paralysed, an atony of the bladder resulting? ("The nerves to the bladder (and vagina) [from the pelvic plexuses] contain a larger proportion of spinal nerves than those furnished to the other pelvic viscera.") 3 Would the retention of feces be accounted for by the failure on the part of the colon to pass the feces on to the rectum, such failure being brought about by paralysis of the intestinal muscles and the automatic plexuses from continual stimulation by the excess of carbonic acid always present in the blood?

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

The Absence of Sugar from Normal Human Urine—Two Cases of Knee trouble with difficulty in Locomotion depending upon an Elongation of the Ligamentum Patellæ, treated by Transplantation of the Tubercle of the Tibia

AN ordinary meeting of this Society was held on Feb 14th, the President, Sir Andrew Clark, in the chair.

Sir GEORGE JOHNSON communicated a paper by Mr G STILLINGFLEET JOHNSON on the Absence of Sugar from Normal Human Urine. Mr Johnson stated that all the tests for sugar in common use depended upon its reducing action, thus in Fehling's test the quantity of sugar was gauged by the amount of cupric oxide reduced by a known volume of the solution. All human urine—normal as well as pathological—exerted some reducing action upon cupric salts in boiling alkaline solutions. Insufficient familiarity with this fact not infrequently led to the conclusion that sugar was present in a sample of urine simply because a certain amount of cupric oxide had been reduced thereby. Non saccharine urines of high specific gravity were especially liable to be pronounced saccharine, because such urines, being highly concentrated, were richer than usual in the normal reducing agents. The object of the author of the paper was to indicate the nature of these "normal reducing agents." A full account of the chemical details of his experiments in connexion with this subject will be found in the Royal Society's Proceedings, vol. xlii., pp 493 to 534. He agreed with Dr Pavy in attributing one-fourth of the reducing action of normal human urine to the uric acid which it contained. He was, however, of opinion that normal human urines were also largely non saccharine, and in proof of this he described his method of separating the kreatinin of urine from that secretion, which differed from all methods hitherto described in effecting a complete removal of that base from the unconcentrated secretion by fractional precipitation with mercuric chloride. The properties of the kreatinin thus isolated were different from those of any base hitherto described, and this difference was especially remarkable when its reducing action was compared with that of other kreatinins. These differences in properties between bases having the same empirical formula were attributed to differences in atomic arrangement—isomerism. Although the method adopted—precipitation by mercuric chloride—could not remove sugar from solution in the urine, the filtrate from the mercurial salt of kreatinin was found in normal urines to be destitute of reducing action, and the determination of the quantity of kreatinin present (by weighing its mercury salt), conjoined with a careful estimation of the reducing action of the kreatinin itself, proved that the entire reducing action of a normal urine might be accounted for by the uric acid and kreatinin which it contained, one fourth of the whole reduction being due to uric acid, and the remaining three fourths to the kreatinin. A beautifully crystallised specimen of the reducing kreatinin of urine was exhibited. In confirmation of Mr Johnson's conclusion that normal human urine was non saccharine, C Schwartz has described a very

delicate test for sugar which gives negative results with normal human urine.¹ This test was exhibited during the evening. It was performed as follows—The urine was completely precipitated with lead acetate and filtered. The filtrate was rendered alkaline with potash and a solution of phenylhydrazine added. The mixture was well shaken and boiled. An orange colour developed, which was followed by an orange precipitate when excess of acetic acid was added if sugar were present. Schwarz states, and Mr Johnson had confirmed his statement, that normal urines gave a negative result with this test. The conclusion was that sugar was absent from normal urine.—Dr WILLIAM HUNTER differed from Mr Johnson in regard to the limitation of reducing action to the uric acid and kreatinin, believing that there were other matters allied to hydrocarbons which effected the same change. He referred to a test with benzoyl chloride which threw down a compound of itself with carbohydrates. It was performed by adding to urine a mixture of 40 c.c. liquor potassæ and 5-10 c.c. benzoyl chloride. He considered that all normal urines contained carbohydrates more or less allied to glucose. One constituent, glycuronic acid, derived from certain articles of diet and drugs such as Borneo camphor, acted as a strong reducing agent. The second, known as the furfural test, consisted in adding to a sample of urine a 15 per cent. solution of a naphthol with 0.5 cc of sulphuric acid, the presence of carbohydrates being indicated by a delicate violet colour. He thought that Mr Johnson's conclusions were only applicable to quantities of sugar sufficient to have a pathological significance, and he did not interpret them as proving the complete absence of this substance in healthy urine. Too much importance should not be attributed to the negative indications of the phenylhydrazine test, as he considered that the reducing capacity of the healthy urine could not be wholly accounted for by kreatinin and uric acid. He commented on the brilliant appearance of the crystals and contrasted their aspect with that of ordinary commercial kreatinin.—Dr CURNOW stated that he had been able, by means of the phenyl hydrazine test, to detect so small a quantity of sugar as one-tenth of a grain in an ounce of urine. The test was, he thought, sufficiently simple to be used for clinical purposes. He adverted to the peculiar globular form assumed by the particles of the precipitate under high powers of the microscope. He had also added to non saccharine urine solutions of urate of potash and of kreatinin in large quantities, and had found that these bodies did not in the slightest degree interfere with the efficiency of the test. It was on this account that he strongly recommended it for ordinary clinical uses.—Dr HAIG welcomed the new test, and quoted a case in which Fehling's solution continued to be reduced by the urine while the patient adhered to a nitrogenous diet, but disappeared on his returning to a mixed diet, and inferred that the reduction of copper was not produced by sugar but by the excess of the nitrogenous extractives.—Dr GEORGE HARLEY referred to the statement made about thirty years ago by Bence Jones that all normal urines contained a trace of sugar, which had been vigorously disputed by other observers, some attributing the reducing power to uric acid, some to kreatinin, and others to undetermined hydrocarbons. Udransky first precipitated the reducing agents by means of benzoyl chloride, Wlenski later separated this precipitate into starchy matters and a trace of grape sugar. He said that Fischer anticipated Schwartz in publishing the phenylhydrazine test. He still adhered to the idea that normal urines were not always free from traces of sugar, its presence depending on the individual and the diet.—Sir G JOHNSON, in reply, said that he had not denied the presence of carbo-hydrates but only of sugar in normal urine. He had separated the reducing agents after measuring the reducing power of the urine and had found that the uric acid and kreatinin exactly accounted for this, leaving no room for any other reducing agents. He accounted for the purity and excellence of the kreatinin crystals exhibited by his methods of separating them which allowed the substance to precipitate gradually from the filtrate after various impurities, such as uric acid, had been brought down immediately by the addition of the mercuric chloride.

Mr WALSHAM described two cases of Knee Trouble depending upon an Elongation of the Ligamentum Patellæ. The first case occurred in a young woman twenty one years old. She complained of pain and difficulty in walking and that she was liable to fall suddenly without warning from the patella slipping over one or other condyle. The falls were so frequent and unexpected that she was incapacitated for her duties as

a housemaid. The patella could be dislocated laterally on either condyle, and with the knee bent at an angle of 90° it could be pushed up on to the front of the condyles of the femur, so that its anterior surface looked upwards instead of forwards. The elongated ligament was shortened by trans-planting the tubercle of the tibia about one inch lower down the shaft. The wound healed by the first intention, and when the patient was last seen the knee joint appeared normal and the patella could no longer be dislocated laterally or pushed abnormally upwards. The second case was in all respects similar and was treated in the same manner. Mr Walsbam had not found the condition described in the surgical text books and in those special works on joint disease that he had consulted, nor was he aware that the transplantation of the tubercle of the tibia for shortening the patellar ligament had been hitherto done. He found that Dr Shaffer of New York had described in the fourth volume of the "Transactions of the American Orthopedic Association" seven similar cases of elongation of the patellar ligament with knee trouble during locomotion. In these cases no operation was performed and the results obtained by instrumental treatment were not satisfactory. Quite recently Mr Walsbam had met with a third case in the Orthopedic Department at St Bartholomew's Hospital and concluded that the condition was not so rare as he had at first believed it to be. He summarised the signs and symptoms in his own and Dr Shaffer's cases and gave his reasons for shortening the ligament by transplanting the tubercle of the tibia instead of excising a portion of the ligament and attempting its union by suture. He thought transplantation of bone with ligaments or tendons attached, might be found suitable for the treatment of other deformities. He had recently transplanted the posterior tubercle of the os calcis with the tendo Achillis attached, for overcoming the elongation of the calf muscles in paralytic talipes calcaneus. A condensed account was appended of Dr Shaffer's published cases.—Mr GODLEE asked whether cases of lateral dislocation of the patella were not of the kind described, and referred to three cases which had come under his observation complicated with knock knee.—Mr KEETLEY mentioned two cases in which there had been abnormal lateral mobility of the patella with tendency to outward dislocation on kneeling. In one case he had removed a wedge of bone from the patella and shortened the internal aponeurosis.—Mr WALSHAM, in reply, said that he had heard from Mr Greig Smith of Bristol of a similar case under his care in which the ligamentum patellæ had been shortened by means of herring stitch sutures.

MEDICAL SOCIETY OF LONDON

A New Method of Treating Oblique Fractures of the Femur without Shortening.—The Physiology of Death from Traumatic Fever, a Study in Abdominal Surgery

An ordinary meeting of this Society was held on Feb 13th, the President, Mr Hutchinson, in the chair.

Mr KEETLEY described an operation for the prevention of shortening and other forms of mal union after fracture, especially oblique fracture of the long bones. It essentially consisted in the insertion of two pins of steel, thickly plated with silver, one into each fragment of the bone, not too near the fracture. Each pin had an arm at right angles to it. These two arms lying outside the skin, were lashed together with silver wire after the fracture had been accurately adjusted. No incision was made, each pin being passed in through a simple puncture. The bones were perforated for the pins by Mr Keetley's patellar bradawl (with a blade three inches and a half long). Two cases were described and one patient shown. Both had sustained fracture of the femur. In one the previous shortening had amounted to one inch and in the other to over two inches. One patient fell and refractured the bone two months after operation but without reappearance of the shortening. In this case the pins had been left *in situ* for six weeks. No pain or rise of temperature occurred in either case. Mr Keetley recommended that the operation should not be resorted to until ten days or a fortnight after fracture, so that there might be time to see what results ordinary modes of treatment were likely to give and also for effused blood to be either absorbed or organised. Of course strict antiseptic precautions should be used, but in an operation which made merely two punctures and required only two or three simple instruments entirely of plated and polished metal such precautions were exception-

ally easy.—Mr HUTCHINSON thought the method suggested was bold, ingenious and likely to be beneficial in some cases, but for his own part he adhered firmly to the long splint with anæsthesia and rather over-extension to the extent of one inch of lengthening. He did not approve of discarding the perineal band, as was done by some surgeons in modern times.—Mr CRIPPS remarked on the fragility of the pins shown. He thought the cases for which they might be applied were very few, and adverted to the danger of perforation by one fragment in the struggles resulting from the administration of an anæsthetic. The spasmodic contraction of muscles subsided by the third day, when the limb could be put up without any great effort.—Mr OPENSHAW was in accord with the remarks already made by Mr Cripps and thought it was an advantage to have the edge of the splint bare and notched so as to exert extension throughout the limb by bandages rather than by the stirrup alone.—Mr KEETLEY, in reply, said he intended the method only for special cases. The want of rigidity of the pins was more apparent than real, and the power required to keep the fragments in position was not great.

Mr JOHN D MALCOLM read a paper on the Physiology of Death from Traumatic Fever, a Study in Abdominal Surgery. The object of the paper was to show that the phenomena of traumatic fever may be explained without assuming the existence of a poison circulating in the blood, and that the changes produced are brought about by peripheral stimulation of nerves acting on the nervous centres—a view already advocated from another standpoint by Dr Hale White. It was pointed out that every injury brings about a devitalisation of tissue with a contraction of the vessels throughout the body, and it was suggested that the want of fresh blood in the area of stasis is the cause of the contraction of the vessels in fever. Papers by Olshausen¹ and Dr Veschere² were referred to as corroborating Mr Malcolm's view that death from ileus and pseudo ileus is an important factor in abdominal surgery. The mode of death from these conditions was discussed. It was urged that distension of the intestine occurring during fever must cause a great increase in the contraction of the vessels already existing in consequence of the operation. Clinical evidence was adduced that the stronger the heart the slower was its action in fever. This was supported by the observation made by Professor Roy and Dr Adami³ that the heart is stimulated by increased resistance in the vessels, and that the cardiac muscle is sometimes more than able to overcome the increased resistance, but sometimes it cannot do so. The evidence in support of Olshausen's and Dr Veschere's view that pseudo-ileus leads to septicæmia was shown to be defective. It was argued that death from fever begins, not at the heart, but at the periphery, and is due to excessive contraction of the vessels shutting off the blood supply from the various tissues. It was pointed out that the blood supply to the inflamed area must also be diminished when the contraction of the arteries is very great, and that this must cause a return of inflammation of an unhealthy kind. It was further argued that when constriction of the blood vessels occurs a necessity arises for the removal of a portion of the blood, which accounts for the sweating and excess of other excretions, and that destruction of blood necessitates more blood formation but that as long as the vessels are contracting elimination must predominate, hence the emaciation. It was shown that devitalisation of tissue in a wound must also induce a physiological coldness and consequent necessity for increased heat locally, hence more heat is produced. The rest of the body then requires increased thermolysis but as long as the local physiological coldness continues an excessive production of heat takes place, though not necessarily resulting in increased body temperature. It was suggested that in the septic and specific fevers the poison circulating in the system produces a wide spread irritation and partial devitalisation of tissue, and reflexly induces the same effects as were attributed to the local devitalisation due to an injury. In such a case, if albuminuria and suppression of urine occur the resistance to the flow of blood through the kidneys aggravates the fever, and may cause death in the same way as the resistance to the flow of blood through the mesenteric vessels does in a pseudo ileus or in obstruction of the bowels following an abdominal section.—[We propose

¹ Centralblatt für Gynæcologie January 1888.

² Revue de Chirurgie July 1888.

³ The Physiology and Pathology of the Mammalian Heart Phil. Trans., vol cxxxvii B., p 270 1892.

to publish the paper *in extenso* in a future issue]—Dr HALE WHITE thought there was no doubt that in some cases traumatic fever was the direct result of peripheral irritation, and mentioned the rise of temperature associated with the passage of a gallstone or the existence of constipation. He referred also to the rise of temperature in meningeal hæmorrhage, in the status epilepticus and hysterical pyrexia, in all of which the absence of bacteriological influence seemed certain.—Mr HUTCHINSON questioned if in the abdominal cases alluded to the absence of peritonitis could be affirmed.—Mr MALCOLM, in reply, mentioned several cases in which no peritonitis could be discovered after death. Referring to some remarks by Mr Alban Doran, he said he excluded cases in which there was an obvious source of septicæmia.

CLINICAL SOCIETY OF LONDON

Subserous Uterine Hematocoele in a Girl aged eleven.—Lipoma of the Broad Ligament.—Diaphragmatic Hernia in which Death was caused by Vomiting.—Generalised Vaccinia

AN ordinary meeting of this Society was held on Feb 10th, the President, Sir Dyce Duckworth, in the chair.

Mr BARKER described a case of Subserous Uterine Hematocoele in a girl aged eleven, simulating Acute Appendicitis, laparotomy was performed with success. Taking the view that the child was suffering from the latter disease in a most typical form, Mr Barker opened the abdomen in the right linea semilunaris over the cæcum, but found the latter and the vermiform appendix perfectly normal. Some turbid, brownish serum, without lymph, flowed from the direction of the pelvis, and feeling in this direction the right fallopian tube and ovary were found to be swollen and twisted, and when brought into view were seen to be quite black from blood effused under their serous coats. Tracing this effusion inwards it was found to expand into a large subserous hematocoele behind the uterus. This tumour nearly filled the pelvis and corresponded with the swelling felt per rectum before the operation. This brownish serum in the pelvis had probably transuded from it, it was quite smooth on the surface and was inflamed. The condition was now recognised, and it was felt that no attempt should be made to remove the blood tumour. The serum was therefore sponged out and the abdomen was closed in the usual manner. The child made an uninterrupted recovery. On leaving hospital on the thirty first day after the commencement of the last attack the hematocoele, as felt from the rectum and vagina, had diminished in size. The patient was watched for a month or two subsequently, but there was no return of the symptoms suggesting any attempt at very early menstruation. The case was recorded as possessing pathological, clinical and surgical interest, and as being probably a rarity, Mr Barker was unable to find any account of a pelvic hematocoele in a girl so young as the patient in question.—Mr TREVES dwelt upon the difficulties referable to the anatomical site in diagnosing appendicitis, and cited two cases illustrating this. One was that of a boy who exhibited all the classical signs and symptoms of intussusception, but on opening the abdomen to relieve the obstruction the condition was found to depend upon gangrene of the vermiform appendix. This was removed and the patient recovered completely. The other case was diagnosed, after consultation between two medical men, as enteric fever and was sent to the Fever Hospital, being subsequently transferred from there to the London Hospital, where the abdomen was opened in due course and the appendix found glued by inflammatory adhesions to the ileum opposite a Peyer's patch, which may have accounted in part for the close simulation to typhoid fever. After removal of the appendix this case also recovered.—Mr BARKER suggested that one advantage about the otherwise objectionable word "appendicitis" was that it directed attention to the real site of lesion, which the older terms did not.—The PRESIDENT considered that the wrong impression prevalent was due to erroneous teaching, and was to be corrected by an improvement in the direction rather than by the introduction of a new and barbarous term.

Mr TREVES gave an account of a large Lipoma of the Broad Ligament removed by operation, and drew attention to the rarity of the affection and to the cases of solid tumour of the broad ligament which had been placed on record.

Dr HALE and Dr GOODHART communicated a case of Diaphragmatic Hernia in which death was caused by vomiting. A man aged forty nine, after much exposure in India, came home complaining of waterbrash with occasional vomiting. No organic disease could be detected. Pain was present at the ensiform cartilage and there was obstinate constipation. In spite of careful dieting, first with milk and farinaceous food and afterwards with peptonised milk, the vomiting became more frequent and profuse and was highly fetid in character. Death occurred apparently from exhaustion. Washing out the stomach gave only temporary relief. Post mortem all the organs were healthy, but the stomach and part of the colon were found lying in the left side of the thorax, having passed through a smooth edged opening in the diaphragm of the size of a closed fist.—Dr GOODHART added that the presence of a tympanic note at the base of the thorax on the left side suggested for a moment the idea of such a displacement, but it was not seriously entertained, especially as the cases already on record had presented quite the opposite condition of dulness. The heart was raised, but was not displaced laterally.—Dr HALE mentioned a case of the same sort at St. Bartholomew's Hospital, in which a tympanic note over the protruded viscus had led to the performance of thoracentesis as for pneumothorax.

Dr COLCOTT FOX read notes of two cases of Generalised Vaccinia. In both the infant was the only one thus affected out of many vaccinated from the same source. In each case the primary vaccination ran a normal course, and about the ninth day the vaccinated arm became covered with a dense aggregation of supplementary vesicles. These were quickly followed by others disseminated singly or in twos and threes over the unbroken skin of the scalp, face, trunk (front and back) and limbs. Fresh lesions evolved for two or three days and then abortive pustular lesions till the twenty fifth day in the first case and till the eighteenth day in the second case. Hardly any scarring resulted and the mucous membranes were free. Dr FOX then referred to the literature of the subject and discussed the arguments for and against the theories of a spontaneous evolution or auto inoculation. The latter could not probably be absolutely excluded as a possible cause in any case, though there were obvious difficulties to meet in some cases. On the other hand, there was evidence that a spontaneous eruption was not improbable, as in inoculated variola, and cow pox was now and again shown to be probably a modified phase of variola rendered non infectious to man.

Dr AGLAND communicated an account of a case of Generalised Vaccinia which had occurred in a child three months old after vaccination with humanised lymph from a perfectly healthy infant, forty one removes from the calf, though supplementary vesicles had developed in an infant four removes back. Three other children had been vaccinated from the one he was describing without any complication. The arm had appeared normal on the eighth day, but secondary vesicles developed in the course of the next five weeks and pustules on the twenty eighth day, the last appearing on the forty second day. The vesicles closely resembled those of small pox, in some developing into small, shallow ulcers, whilst the original ones coalesced and formed a large ulcer under a continuous scab. There was no infiltration of glands. The child died on the forty ninth day. The mother, who had not been revaccinated, contracted the disease on the nipple. Dr AGLAND said the clinical history was that of generalised vaccinia and drew attention to the lateness and persistence of the eruption. The condition might have been due to swallowing the lymph since the lips had become inoculated, or to absorption from the original vesicles on the arm.

Dr BARLOW thought such cases were very rare, and referred to a case of vaccinia gangrenosa described in the Royal Medical and Chirurgical Society's Transactions. He drew attention also to the papular eruption like the first stage of small pox, which affected the extremities in many cases after inoculation with calf lymph.—Dr CHAPMAN considered the effects of calf lymph were far more severe than those of the humanised variety.—Dr LINGSTAFF thought the severity of the changes were due to the vesicles being too close together, and recommended a single puncture on each arm.—Dr COLCOTT FOX thought such cases might be more common than was generally believed. They were not apparent to most vaccinators because they occurred after the eighth day. He thought patients should be under observation until their sores were healed.

OTHER METROPOLITAN MEDICAL SOCIETIES

HÆMELIAN SOCIETY OF LONDON—An ordinary meeting of this Society was held on Feb. 2nd, Mr Malcolm Morris, President, in the chair. Mr EDMUND OWEN read a paper on Post-nasal Growths in Children and showed two children with widely cleft palates, in whose throats the normal pharyngeal tonsil could be clearly seen. As regards the diagnosis of the affection, he thought that the long and vacant looking face, the open mouth, the thin and compressed nostrils, the inability of the child to breathe through the nose, and the "stuffy" and dead voice were more than enough to establish proof of the disease. By curling the index finger round the soft palate the vegetations could be felt in the naso-pharyngeal cavity were further proof of their presence required. In children, at least posterior rhinoscopy was unnecessary, the mirror could teach the finger nothing. As regarded treatment he urged the prompt removal of the hypertrophied tissue.—Mr BUTLIN had been in the habit of operating under anaesthetics and generally preferred chloroform. At first he had always placed the patient in the supine position but during the last three or four years his patients had been placed on the side during the operation, with the thighs flexed and the head a little forward and on a low pillow. The blood then ran forwards into the cheek and could be constantly removed without interfering with the operation. He had had one fatal case in about 750 operations.—Mr LENOX BROWNE, in answer to the very pertinent question of Mr Edmund Owen "How did children get on before the discovery by Meyer of adenoid vegetation as a cause of deafness?" said that removal of enlarged tonsils alone exerted a certain, and in some cases a remarkable, improvement in the hearing. As in at least 90 per cent of the cases of enlarged tonsils adenoids also exist, he (the speaker) had made it a fixed rule always to search for adenoids and if present to remove them as an essential part of the operation of ordinary tonsillotomy.—Mr T MARK HOVELL, who showed a finger guard, cut from a piece of thick india-rubber tubing, which he used whilst examining patients for adenoid growths, said he found that without an anæsthetic some part of the growth was liable to be left and so to keep up middle-ear catarrh but he now always employed an anæsthetic. He preferred, except in the case of young children, to begin with gas and pass on to ether, and subsequently to use chloroform administered by means of a Junker's inhaler.—Dr SCANES SPICER considered that sufficient attention had not been given to the prevention or arrest of enlargements of the pharyngeal tonsil. These were largely the result of long standing congestion in a tissue specially liable to hyperplasia in early life, and the congestion was the consequence of some obstruction, organic or temporary (catarrhal) in the nasal passages. In an obstructed nose, through which the air could yet pass, each act of inspiration led to diminished intra nasal and naso-pharyngeal pressure posterior to the obstruction.—Dr FELIX SEMON whilst admitting that digital exploration was indispensable for diagnostic purposes in small children, had found that in somewhat older children posterior rhinoscopy often fully replaced the first-named certainly unpleasant investigation. He described the method of operation of which he was in the habit of availing himself (head but slightly hanging over the edge of the table, slight chloroform narcosis usually Gottstein's curette, and only very occasionally forceps) and finished by observing that in his experience in no class of cases was a repetition of the operation more frequently required than in those in which the finger nail had been used.—Dr SILK, speaking as an anæsthetist said he had used nitrous oxide and ether in a large number of cases but had come to the conclusion that this combination distinctly increased the loss of blood especially when the patient was lying down.—Dr WILLIAM HILL considered that a more scientific name for these growths—viz. 'hypertrophy of the pharyngeal tonsil'—should be adopted.—Dr WILLIAM HOLLOWAY spoke in favour of the sitting posture.—Mr OWEN replied.

HUNTERIAN SOCIETY—The annual general meeting of this Society was held at the London Institution on Feb. 8th, when the following officers were elected for the ensuing year.—President Mr Frederick Gordon Brown. Vice-Presidents Mr Thomas E. Bowkett, Sir Andrew Clark, Bart. Dr J. Dundas Grant, Mr John Poland. Treasurer Dr F. Charleswood Turner. Trustees Mr H. Fotherby and Mr F. M. Corner. Librarian

Dr Arthur T. Davies. Orator for 1894 Dr J. Dundas Grant. Secretaries Dr R. Hingston Fox and Mr T. Horrocks. Openshaw. Other Members of Council Dr Alexander Burger, Dr F. J. Smith, Dr E. C. Perry, Dr G. Newton Pitt, Dr Geo. E. Yarrow, and Messrs W. Percy Reynolds, H. W. Denton Cardew, T. Mark Hovell, Henry J. Thorp, Francis R. Humphreys, Alfred H. Tabby and Percy Warner. The Annual Oration was afterwards delivered by J. S. E. Cotman, M.R.C.P. Ed., who had chosen for his subject "Physical Education." Diagrams and apparatus were exhibited in illustration of the theme. The Fellows and friends of the Society dined together at Wood's Hotel on the 10th inst.

WEST LONDON MEDICO CHIRURGICAL SOCIETY—At the meeting on February 3rd, the President, Mr F. SWINFORD EDWARDS showed a specimen of Sarcoma of the Hand, and another of Carcinoma of the Rectum.—Mr R. F. BENHAM exhibited a Growth at the Back of the Orbit following Dislocated Lens.—Dr HENRY SUTHERLAND then demonstrated Various Methods of Artificially Feeding the Insane. The modes of feeding by the mouth which could be practised by the attendants were—(1) by spoon, (2) by two spoons, (3) by feeding cup, (4) by spoon and feeding cup, and (5) by Paley's feeder. The modes of feeding by the nose were (1) by spoon, (2) by feeding cup, and (3) by funnel. The modes which should be employed by a medical man only were by the mouth, stomach tube, and by the nose (nasal tube). The advantages and disadvantages of each were explained and the various methods were shown, a professional "sword swallower" being the subject chosen for operation.—Dr ARCHIBALD GARROD read a paper on Chlorosis. The uniformity of type and almost constant character of the symptoms of chlorosis were noticed, and he then proceeded to discuss the more conspicuous symptoms of the disease as seen amongst hospital outpatients. Several members of the Society joined in the discussion which followed.—Drs BARRY BLACKER and R. H. CLARKE communicated a paper on Light from a Medical Point of View. They referred, firstly to the effects of light upon plants and upon the sickly inhabitants of narrow courts and dark, mountainous valleys and pointed out that in climatic cures sunlight was the one indispensable factor, all other conditions and especially that of temperature, being variable. Pigmentation, the most interesting result of exposure to the sun, was due to the action of light though black pigment was disadvantageous to its possessor as regarded heat. The negro was pigmented in order to resist the excessive stimulus of light. Exposure in bright, cold weather was followed by tanning and irritation of the skin, of the conjunctiva and retina, effects which might be produced by light quite apart from high temperature. The effect of electric light upon the peripheral nerves according to the evidence of Mr J. E. H. Gordon, supported by the experiments of Dr Maklakoff of Moscow was probably that of stimulation. Drs Blacker and Clarke considered that the application of sunlight, and possibly also of electric light, to the whole surface of the body might be employed as a stimulant to the nervous system.

PROVINCIAL MEDICAL SOCIETIES

BRADFORD MEDICO CHIRURGICAL SOCIETY—Dr J. H. Bell presided at the meeting on Feb. 7th, when Dr MOORHEAD showed a boy, aged six, the subject of Disseminated Spinal Sclerosis. At the age of fourteen months the child seemed healthy, there was no injury nor were there fits, but at two and a half he became easily tired, began to drag the toes and had difficulties in speech. Later pain and coldness of the feet were complained of, and spastic gait became marked. Now there is no tremor, vertigo, nystagmus, or amblyopia, the deep reflexes are exaggerated, ankle and rectus clonus being present, and the cutaneous reflexes normal.—Mr FIRTH read notes and showed specimens from two cases in which the spine had been dislocated and fractured between the fifth and sixth and sixth and seventh, cervical vertebrae respectively. In one an attempt was made to reduce dislocation without relief to symptoms.—Mr PETTIT described a case of Tumour of Optic Thalamus and showed preparations from a girl, aged five, who had suffered a slight scarlet fever attack about three months previously followed in ten weeks by dragging of the right leg, feebleness of the right hand and internal nystagmus on the right side. A week later other morbid conditions supervened, and death followed.—Mr HORROCKS reviewed the prescribed teaching in relation to the

Surgical Treatment of Cancer of the Breast and dealt also with the anatomy and relations of the gland. He advocated the old method of wide and extensive removal of the breast. In doubtful cases exploratory incision was required.—Dr RABAGLIATI had followed out cases of his earlier years and found they all succumbed in about three years. He thought he would revert to the old plan of completely altering the constitutional conditions.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—On Jan 25th, Dr Pollok, President, in the chair, Dr LINDSAY described three cases of Malformation of the External Genital Organs occurring in one family, and showed one of the children. He was of the opinion that all were hypospadiac males, although two of them had been brought up as girls. The parents and six other children of the marriage were naturally formed.—The PRESIDENT then read a paper on the Prophylaxis and Treatment of Abortion. He said that there was a popular belief that very early abortions required neither care nor attention, but he was inclined to emphasise the very opposite—viz., the earlier the abortion the longer rest and the more care needed. He classified the causes under five headings—traumatic, mechanical, neurotic, toxicæmic, and inflammatory. In discussing the treatment he dwelt upon the necessity of thoroughly emptying the uterus. He had always found it very difficult to do this with the finger, and he had found ovum forceps a failure. If rest and sedatives failed to prevent abortion, he plugged, and after from twelve to twenty fours usually found the complete ovum come away on removing the plug. When there was retention of a portion he dilated with Smith's metallic bougies and employed the curette. After douching he mopped out the cavity with perchloride of iron to arrest hæmorrhage and inserted a strip of iodoform gauze in such a way as to plug the vagina. This was removed in twenty four hours and an antiseptic douche used night and morning.

MANCHESTER MEDICAL SOCIETY.—On Wednesday, Feb 1st, the President-elect, Dr GLASCOCK, at the request of the committee, delivered an inaugural address on "Brief Notes on the Materia Medica of the Ancient Egyptians with reference to Eye Diseases." The address was well received, and after its delivery Dr S. HOLGATE OWEN mentioned two cases of the milder form of Raynaud's disease. In each the disease manifested itself by the "dead fingers" and by symmetrical patches of "local asphyxia" on the front of the legs. Purpuric spots also occurred on the thighs. Both cases were in women, and in one the symptoms were preceded by an attack of hysterical paralysis. Dr Owen drew attention to certain points of similarity between this disease and tetany, both as regards etiology and symptoms.

NOTTINGHAM MEDICO CHIRURGICAL SOCIETY.—This Society met on Feb 1st, Mr R. C. CHICKEN, F.R.C.S., President, in the chair.—Dr KINGDON showed a case of Congenital Fibroma involving the right eyelid and zygomatic region.—Dr HANDFORD brought forward a woman aged twenty nine with Lupus Erythematosus of the dorsal surfaces of the fingers of both hands.—Mr ANDERSON showed a case of Epithelioma.—Dr CATTLE read for Dr STAFFORD notes of a case of Pulmonary Embolism. A woman aged thirty six was seized during the eighth month of pregnancy with intense dyspnoea, signs of cardiac failure and rusty expectoration. Labour occurred at the normal term and the patient completely recovered. He also read for Dr STAFFORD notes of a case of Chylous Ascites in a man aged sixty five, who suffered for ten years from temporary glycosuria, gastric and hepatic symptoms, hæmatemesis and melæna.—Dr THRESDER read a paper on suggestions bearing on Preventive Medicine applied to dwelling houses. He also read notes of three cases of Friedreich's Disease occurring in members of the same family. The disease commenced about puberty. In all three there was marked ataxia, absence of lightning pains and slow speech. Knee jerks were present in two cases, and in two others there was a slow form of nystagmus.—Mr PAUL showed for Mr HATIERLY the Uterus removed by Porro's operation from a dwarf three feet eight inches in height and aged twenty three. The patient was much deformed by rickets, the conjugate of the pelvis measuring an inch and a half. The patient recovered without a bad symptom. The child was alive.—Dr HEELIS showed a Piece of Metal which had been embedded for some time in the scalp of a young woman and had caused obscure symptoms.

SHEFFIELD MEDICO CHIRURGICAL SOCIETY.—At the meeting on Jan 25th, the President, Mr Simeon Snell, in the chair, Mr ARTHUR JACKSON read the notes of a case

of Cancer of the Breast in a man.—Dr SINCLAIR WHITE showed a youth, aged eighteen, with Congenital Hydrocele.—Dr HUNT showed two Dermoid Cysts which had been removed by Mr Arthur Jackson from a woman twenty nine years of age. The patient made a good recovery.—Dr HAMIL read notes of a case of Ruptured Kidney in a woman aged twenty two, who had suffered from lead poisoning. She was found alone and unconscious, and it was supposed that she had been the victim of an assault. At the post-mortem examination all the organs were found to be healthy with the exception of the left kidney in the middle third of the posterior surface, of which there was a laceration nearly an inch in length.—Dr GWYNNE read a paper on Diarrhoea in Children. He deprecated a minute classification of diarrhoea as anatomically unsound and clinically valueless. In the treatment of epidemic autumnal diarrhoea delay was dangerous in very young children. In such cases he would at once stop the milk supply. He was sure of the good effects of calomel or mercury with chalk, with small doses of Dover's powder, and irrigation of the bowels with warm water containing tannic acid or acetate of lead. Erosions of the mucous membrane and innumerable small ulcers were well marked over most of the large intestine.—The President, Dr Sinclair White, Dr Samson Mathews, Dr Arthur Hall, Mr Wightman, Dr Martin and Mr Dale James joined in the discussion which followed.

WEST KENT MEDICO CHIRURGICAL SOCIETY.—The meeting on Friday, Feb 3rd was devoted to the exhibition of clinical cases, Dr Pitt, President, being in the chair.—Dr GARTH showed for Mr Poland a man who had made a good recovery after operation for Strangulated Congenital Hernia, with removal of sac. He also showed a woman, aged seventy with Epithelioma of the Upper Lip.—Dr PITT exhibited a pathological specimen of Arterio venous Aneurysm formed by the left iliac vein and aorta at its bifurcation. He also showed Spinal Cord Sections from (1) Ataxic Paraplegia, (2) Charcot's Disease of Knee, (3) Infantile Paralysis, (4) Syringomyelia, with Glioma of Cord.—Dr ERNEST CLARKE showed a piece of steel 2 mm square and 0.5 mm thick, which he had removed from beneath the conjunctiva on the under surface of the left upper lid of a man, where it had remained for twenty two years.

Reviews and Notices of Books.

Médecine et Mœurs de l'Innocence Rome d'après les Portes Latins. Par le Dr EDMOND DUPUY. Deuxième Édition, Revue et Corrigée. Paris. Baillière et Fils. 1892.

Syphilis in Ancient and Prehistoric Times. By Dr F. BURET. Translated from the French, with Notes, by Dr A. H. OHMANN DUMESNIL M.D., Professor of Dermatology and Syphilology in the St. Louis College of Physicians and Surgeons. Vol. I. Philadelphia and London. T. A. Davis. 1891.

WE have bracketed these two publications together as dealing, on the whole, with the same subject, though, as will be seen from their respective titles, Dr E. Dupuy confines his strictures to Ancient Rome, whilst Dr Buret extends his observations to the whole world of antiquity. Neither is addressed "virginibus puerisque," but rather to those of the profession who interest themselves in the pathological sequelæ of vices common to every period of the world's history.

Dr Dupuy calls his book a "second edition," but, except for the omission of some very inaccurate engravings representing the "baths of antiquity" we see little difference between it and the first, published in 1885 and already noticed in THE LANCET. There are the same number of pages and nearly the same misprints in each. At p. 12, for example the "tumentibus" of the first edition has not been corrected into "tumentibus" in the second, at p. 13 "anellitus" and "venis" still do duty for "anbellitus" and "ventis", and at p. 16 "pantherum" and at p. 18 "ern" continue to violate sense and quantity alike. Even in the first paragraph of the preface an astounding historical blunder is allowed to remain—"Antonius Musa, Plinio l'Ancien, Artète et Cælius Aurélianus apparnissent presque en même

temps que l'Hippocrate latin." By the "Latin Hippocrates" the author means Celsus, and he asks us to believe that that writer, whose date is that of the Emperor Tiberius (A.D. 14-37), was nearly contemporary with Aretæus, whose "floruit"—according to the best authority—is at least a hundred years later and with Cælius Aurelianus, who lived at the end of the fourth, or more probably in the first half of the fifth, century A.D. After this stumble on the threshold it is hardly likely that the author's subsequent progress can be very satisfactory. Under Martial, for example, we find him ignorant of the changes wrought in the criticism of that author by Friedländer's monumental edition (1885), whilst the badly accented Greek and the false quantities that disfigure the extracts in the first issue of his treatise are still maintained in the second. For those who can tolerate such *maculae* the book is not without interest, gathering together as it does and conveying in a clear even viraciously style a great mass of detail on the immoral life of antiquity and on the pathological and therapeutic doctrine for which that life supplied the material. But to earn the favour of more exacting and scientific readers it must be thoroughly revised by the light of better texts and more recent commentaries than the author seems to have consulted.

The second publication is much more elaborate, though it cannot, any more than the first, be considered to reflect the latest and best scholarship. On the origin of the word "syphilis" Dr Buret has no light to shed. Instead of following the sound lead of the great philologist and physician Littré, according to whom "on ne connaît pas l'étymologie de ce mot," he falls back on the exploded etymology from *σφ*, with, and *φύλα* love. He then seeks to trace the disease back to ancient times when again his authoritative compatriot could have told him, "on ne rencontre aucune indication précise de la syphilis proprement dite dans les médecins de la Grèce et de Rome et cela jette le doute sur ce point d'histoire médicale." Unadmonished by this dictum he goes back even to prehistoric epochs, and by a catena of extracts from previous writers, the majority of whom carry no special weight he finds syphilis amongst the Chinese "five thousand years ago amongst the Japanese the Egyptians, the Assyrians and Babylonians, the Hebrews and, *a fortiori* amongst the Greeks and the Romans. It awakens more than suspicion as to his inductions when we find that none of the really great historians of medicine—Häser for example, or Puschmann—venture to extract from his citations the precise references to syphilis he himself does, and our suspicions are confirmed when we find him quoting as a decisive authority that translation of the Ayurveda by Hessler which Häser expressly cautions his readers against as 'sehr mangelhaft' (very defective). When we come to classical antiquity we find his special pleading and his love of "broad translation" as he calls it, still more marked, no doubt because he is treading ground already carefully traversed by scholars who have failed to 'read into' his authorities the meanings he discovers in them. Take, for instance his interpretation of the well known passage in Thucydides (II. 49) describing a symptom of the plague at Athens. One of the last stages of that disease, says the historian, was its attack on the extremities, including the pudenda, and this latter circumstance is actually pressed by Dr Buret into the service of his argument that syphilis must have been a factor in the plague! Not more fortunate is he in his Roman chapter, where he makes Horace (Odes I., 37) contribute to the thesis that syphilis must have been common in his times. The lines are familiar to all, but we venture to say that no editor of authority has interpreted them in Dr Buret's sense. The reader has but to refer to Hirschfelder's revision of Orelli's Commentary (Berlin, 1886) to bear out our criticism. Nor is he any more fortunate in his appeals to Martial, of whose one

good editor (Friedländer) he seems to be ignorant. Many passages he no doubt adduces from that exceedingly plain-spoken satirist of the Rome of Domitian, but he cannot lay his finger on one which can be accepted as sustaining his thesis. At the same time the book is not without value for the fidelity with which it depicts the immoral side of antiquity, and to all who are not nauseated by such details it has a certain interest of its own.

The Year book of Treatment for 1893 A Critical Review for Practitioners of Medicine and Surgery London Cassell and Company

WHEN a book such as this has reached the ninth year of its existence the work of criticism becomes an easy task. Changes of contributors and of arrangement have to be noted, and the method of each contributor has to be considered with reference to past work. The changes are few. Death has removed Dr James Ross of Manchester from association with Dr E. S. Reynolds in the preparation of the section dealing with diseases of the nervous system, including insanity. Two new contributors have been added—Dr Dudley Buxton who has charge of an article on Anæsthetics, and Professor W. H. Corfield, who writes a separate article on Public Health and Hygiene. Space has been found for these two new articles, partly by condensation (which affects mainly the articles upon Diseases of the Heart and Circulation and upon Diseases of the Lungs and Organs of Respiration) and partly by a new arrangement of the selected list of new books, new editions and translations, by which some ten pages have been saved. On the other hand the articles upon Infectious Fevers and Diseases of the Skin have notably increased in length, so that the absolute bulk of the "Year-book" is increased by some ten pages—a small matter when the importance of the new articles is considered.

In dealing with Diseases of the Heart and Circulation Dr Mitchell Bruce follows a new "natural order" of arrangement which is fully adequate to the materials he has to work upon. The chief interest centres round the use of digitalis, its active principles and its succedanea. Dr Markham Skerritt writes of the Diseases of the Lungs and Organs of Respiration, the treatment of pneumonia with oxygen gas and the hygienic and constitutional treatment of pulmonary tuberculosis being the main topics of discussion. The article upon diseases of the nervous system, including insanity, is now in the sole charge of Dr E. S. Reynolds of Manchester, who finds abundant material in the various remedies suggested for the treatment of insomnia and for the relief of pain. Dr R. Maguire writes the article upon Diseases of the Stomach, Intestines and Liver, while the article upon Diseases of the Kidneys, Diabetes &c. comes from the pen of Dr C. H. Ralfe, who devotes most attention to diabetes though he mentions at length the Croonian lectures of Sir William Roberts, reference to the same lectures recurs in the article upon Gout and Rheumatism, by Dr A. E. Garrod. Dr Sidney Phillips deals with Infectious Fevers. The short article upon Anæsthetics, by Dr Dudley Buxton, introduces some useful novelties. Mr Stanley Boyd's contribution on General Surgery is long, but the subject is treated with lucidity. Mr W. J. Walsbam writes the article on Orthopædic Surgery and regrets the paucity of material in this department. The article on Surgical Diseases of Children, by Mr Edmund Owen, displays many characteristic indications of his keen criticism. Mr Reginald Harrison, Mr Alfred Cooper and Mr Ernest Lane respectively write efficient articles upon Diseases of the Genito Urinary System, Diseases of the Rectum and Anus, and Venereal Diseases. The work of Dr G. Ernest Herman, Dr M. Handfield Jones, Mr Malcolm Morris, Mr Henry Power, Mr G. T. Field and Mr Barclay J. Baron is also highly commendable. The Summary of the Therapeutics

of the Year, by Dr W G Smith, contains a curious misprint (many times repeated) which appears to cast doubts upon the alkaloidal nature of cocaine. Professor Corfield's article on Public Health and Hygiene is admirable as a summary of the hygienic work of the year, but it does not give many references to the sources of information. Viewed as a whole, the

Year book of 1893" is a satisfactory production fully equal to previous editions, and the numerous writers engaged on the compilation are to be congratulated upon having completed a work of such general utility.

LIBRARY TABLE

The Journal of Physiology Edited by MICHAEL FOSTER and Others. Vol XIII. Supplementary Number. Cambridge Engraving Company, Cambridge. December, 1892.—In a slip issued with this number of "The Journal of Physiology" it is stated that the increasing supply of material accepted as suitable has led the editors to issue a volume no longer, as heretofore, annually, but as soon as about 500 pages have been completed. This augurs well for the progress of physiology in Great Britain, and if the quality of the memoirs and articles published be maintained at the present high standard the journal may continue to rank with the best foreign periodicals devoted to the same subject. The present part contains the following papers: (1) On the Relation of the Posterior Root to the Posterior Horn in the Medulla and Cord, by H. Tooth, (2) On the Larger Medullated Fibres of the Sympathetic System, by J. N. Langley, (3) A Method of obtaining the Specific Heat of certain Living Warm blooded Animals, by W. Hale White, (4) On Lacto globulin, by R. T. Hewlett, (5) Does Bone contain Mucin? by R. A. Young, (6) The Proteids of Liver and Kidney Cells, by W. D. Halliburton, (7) The Influence of Light on the Gas Exchange in Animal Tissues, by C. A. Ewald, (8) Graphic Records of the Action of Chloroform and Ether on the Vascular System, with a plate, by J. A. MacWilliam, and, lastly, the Effects of Drugs and other Agents upon the Respiratory Movements, by H. O. Wood and D. Cerna.

The Practical Guide to Algiers By GEORGE W. HARRIS, Third Edition, thoroughly revised up to date and enlarged. London: George Philip and Son. 1893.—The rapid sale of two considerable editions of this compact little book attests the favour with which it has been received by the travelling public. The demand for it also shows the increasing attraction Algeria possesses as a winter resort. Algiers itself is gradually receding into the background in this respect, and now that the railway is extending southward it is to Biskra, "the Queen of the Desert," that "seekers for sun" are drawn in ever greater numbers. Mr Harris rightly claims for Biskra a "climate without parallel." When London is wrapped

in fog and Paris mantled with snow, when both Rivières—the Rhodane and the Riviera Levante—are swept with snow, and the Alps or Apennines, Biskra remains a warm land with a temperature between 70 and 80 F° overhead and a glorious land for the visitor to the green oasis and the like, to portion time, the attractions were not

STONHAM, F.R.C.S. 1892.—This descriptive catalogue has been compiled by Mr Charles Stonham, assistant surgeon to the hospital. Seldom, if ever, have we met with a museum catalogue so excellently prepared in every way. By means of a full index at the commencement of the volume we are able to turn at once to any class of specimens we wish to refer to, and in finding it obtain full information. Mr Stonham modestly states in his preface that he has "endeavoured to explain by short headings the chief morbid lesions to be met with in the various pathological processes which the specimens illustrate, believing that by this means the student of morbid anatomy will more readily obtain a fair grasp of the subject of fundamental importance in the rational study of disease." In attempting this Mr Stonham has made the "catalogue" a most valuable work of reference, and all future students will have to thank him for making their studies in this direction easy and profitable. We congratulate him on the success of his labours, and trust that the compilers of similar catalogues at other hospitals will adopt his excellent suggestions.

Cottage Sanitation By HECTOR McLEAN WILSON, M.B., B.Sc. With Preface by T. PRIDGIN TEALE, F.R.S. Published by the Royal Agricultural Society of England, 12, Hanover square, London, W. 1893.—This excellent little pamphlet is the outcome of a meeting of several experienced medical officers of health. It is drawn up by Dr H. McLean Wilson, under the supervision of Dr Cameron and Mr T. Pridgin Teale, from notes taken at the meeting. The paper contains fourteen illustrations, which very clearly illustrate the text. The aim of "Cottage Sanitation," as described in the preface, is to make suggestions of as simple a kind as will meet the necessity of each case, and to set forth a minimum of sanitary requirement such as may reasonably be attained in every country village. The pamphlet is a cheap reprint, for distribution in rural districts by sanitary and parochial committees. It is 3d per copy or 2s per dozen, and is well adapted to serve the purpose which its publication is designed to fulfil.

The Veterinary Journal. London: Baillière Tindall & Cox.—The number for January well maintains the reputation of this useful journal, by the value and interest of the articles it contains. Amongst the original communications is one on the Koch test for tuberculosis in cattle, which affords strong evidence in favour of tuberculin as an aid to the diagnosis of that very serious disease in bovines. The paper is by Professor Armsby of the Pennsylvania State College. There is another on opacity of the hyaloid membrane of the vitreous humour in a horse's eye, and there are several very interesting papers on other matters connected with animal medicine and surgery, home and foreign.

Dod's Peerage, Baronetage and Knightage of Great Britain and Ireland for 1893. London: Whittaker and Co. and George Bell and Sons.—We have received a copy of this useful index to the titled classes of the United Kingdom and to the colonial, diplomatic, military, naval and civil service officers of the State. The work—which is too well known to need any description from us—has now attained its fifty-third year of publication and has been brought up to date, the appointment of Sir J. P. Caron, K.C.M.G., to the Postmaster Generalship of the new Canadian Ministry being the last entry. An obvious printer's error occurs on the contents page at the fourth line from the bottom, where "Colonial Precedence" should evidently be "Clerical Precedence."

Kelly's London Medical Directory for 1893. London.—It may be supposed, the fifth year's issue of this work, which has just come to hand, varies but little from the preceding volume save in the necessary addition of fresh names. The enumeration to a larger extent of the works added by the respective authors will no doubt be useful.

Analytical Records

FROM

THE LANCET LABORATORY

DIURNULES

(PARKE, DAVIS AND CO, NEW YORK.)

RECOGNISING the inconvenience which the physician often meets with when he wishes to prescribe ordinary minimum or maximum doses of such bodies as the alkaloids, glucosides and similar principles the above firm of manufacturing chemists subdivide the maximum full daily dose of the substance into twelve small equal doses. In the shape of granules the medicaments thus subdivided are designated, not inaptly, "diurnules," which are distinguished from parvules, pink granules and regular white granules by a yellow coloured coating. The prescriber has therefore but to remember that twelve diurnules represent the full daily adult dose of the different medicaments as exhibited in that shape. The condition of the patient, of course will lead him to vary the dose from one diurnule every two hours to one every three, four or six hours, in accordance with the requirements. We have recently received for inspection and examination a pocket case, elegantly finished in morocco containing in the form of diurnules twelve typical substances. Notwithstanding the minute quantity of medicament which is contained in many of the diurnules, we have not failed to isolate and recognise the principle in any single example, although one diurnule only was operated upon for this purpose. This bears testimony both to the reliability of the preparations and to the delicacy of chemical tests. In the case of the atropine sulphate diurnule, for instance, twelve of which contain $\frac{1}{10}$ gr of the sulphate—one diurnule ($=\frac{1}{120}$ gr) responded distinctly on proper treatment to the test known as Vidali's, which depends upon the production of a violet colour when the extracted alkaloid is evaporated with nitric acid and afterwards moistened with alcoholic potash. A single diurnule of arsenious acid, again, containing only $\frac{1}{10}$ gr, yielded all the characteristic reactions of arsenic. The aconitine diurnule, containing only $\frac{1}{10}$ gr of the alkaloid base, gave a residue when suitably treated which produced the peculiar numbing sensation upon the tongue. Similarly, sufficient alkaloid (quantities varying from $\frac{1}{10}$ gr to $\frac{1}{120}$ gr) was contained in the diurnules of morphine, gelsemine, strychnine, physostigmine and other bodies to admit of their recognition by chemical means. Diurnules are obviously models of pharmaceutical elegance and efficiency and they serve admirably to illustrate the assistance which pharmaceutical skill affords the physician in attaining accuracy of dosage and ease of administration.

LENTILINE BISCUITS.

(E. MARRIOTT AND CO HATFIELD ROAD HASTINGS.)

Chemical analysis assigns to lentils an extraordinary nutritive value, inasmuch as they contain twice the amount of proteids contained in wheat flour, the same amount of fat, 12 per cent. less starch, and 1 per cent. more mineral matter, in which iron and phosphates abound. The composition, texture and flavour of the above biscuits are alike excellent, the peculiar taste of the lentil blending remarkably well with that of the entire wheat meal. Both cereals were readily recognised under the microscope. The biscuits afford a portable and palatable form of one of the most nutritious pulse foods.

MALTO PEPSIN

(HAZEN MORSE, TORONTO CANADA, AND MESSRS BURGOTTE, BURRIDGES & CO, 16, COLEMAN STREET E.C.)

In this preparation are skilfully combined the digestive agents pepsin, pancreatin and diastase (exsiccated extract of malt) with the acid lactophosphate of lime. The presence of

lactophosphate of lime was confirmed on analysis, whilst about the activity of the digestive principles referred to there can be no doubt. Thus, white of egg was rapidly converted into peptone, and starch into dextrine and sugar. Apart from its trustworthy nature as an efficient aid to digestion, malto pepsin may also be regarded as possessing properties which make it of tonic value. The formula is an excellent one.

CAFFEIN S LIQUOR CARNIS

(THE LIQUOR CARNIS COMPANY 50, HOLBORN VIADUCT E.C.)

This valuable food has on a previous occasion found a place in our records of analytical work. It has since been considerably improved in many essential respects, not the least of which are flavour, keeping properties on exposure to air, and mode of manufacture, in which, it should be added, provision is made to secure the product against all risk of infection. With regard to analytical results they are as satisfactory as before. The moisture amounted to 55.40 per cent., the meat extractives and carbohydrate menstium to 42.07 per cent. (containing 4 per cent of nitrogen) and the mineral matter to 2.20 per cent., consisting chiefly of valuable phosphates with a minimum of common salt. The excellent state of preservation of the vital principles of beef is apparent from both chemical and spectroscopic examination. The albuminoids of the meat for example, are present in an unaltered state, as is evidenced by the preparation becoming solid on heating, and a diluted solution exhibits the characteristic absorption spectrum of fresh hemoglobin, the two lines disappearing from the solution on boiling. Liquor carnis is free from objectionable preservatives and, having regard to its high nutritive value, is really a powerful as well as an economical food and restorative.

GRANULATED OATMEAL.

(SMITH AND SONS MID CALDER, MIDLOTHIAN.)

We must express approval of the process by which this excellent meal is produced. It is a granular preparation and the grains are of equal size, so that it may justly be claimed that the operation of cooking would be more uniform and complete—a matter of some importance especially where enfeebled digestions are concerned. Furthermore, the meal is entirely free from husk and possesses an excellent oatmeal flavour. It is evidently the refined product of a valuable food.

BLAUD'S PILLS

(SOUTHALL BROTHERS AND BARCLAY BIRMINGHAM.)

The real value of a Bland's pill depends of course upon the amount of ferrous carbonate it yields on double decomposition. In this respect we find the pills of the above firm satisfactory both the amounts of iron and alkaline carbonate in which were determined by analysis. The iron is almost entirely present in the ferrous condition, whilst the alkaline carbonate was slightly under the amount necessary to completely decompose the ferrous salt. The pills keep perfectly but the coating is, we find, a somewhat hard substance and liable to crack.

DIABETIC FOODS

(ROBERT MCVITTIE, 23-25 QUEEN'S-FERRY STREET EDINBURGH.)

From each and all of these preparations it is claimed that starch has been carefully excluded. They comprise gluten rolls, gluten bran rolls, gluten and almond bread, almond biscuits and imitation oatcake. In the first three mere traces of starch were found, but in the almond biscuit and the imitation oatcake results of an absolutely negative kind were obtained on testing. With regard to palatability the oatcake is especially to be commended, the bran rolls and the almond biscuits coming next in this respect. It is very satisfactory to observe the attention which manufacturers are now directing towards the improvement of the flavour and character of the food intended for the use of patients suffering from diabetes. The above-named preparations afford evidence of this.

THE LANCET.

LONDON SATURDAY, FEBRUARY 18, 1893

THE lecture on Antiseptics given by Sir JOSEPH LISTER in the London Post graduate Course was a demonstration not merely of the system with which that surgeon's name has been associated, but of the enormous advances that have been made in surgery during the last couple of decades, and finally of the scientific accuracy of almost every observation and prediction made by him as the initiator of the system. Anyone who has followed the development of antiseptic surgery must be struck by the almost marvellous continuity of the original idea throughout every step. The end to be attained was at the very outset stated to be the same as is now known to be necessary, the only real progress that has been made being in the direction of eliminating unnecessary complications and of using materials which will give the desired result whilst exerting the least possible deleterious influence on the skin and exposed tissues, and it must be confessed by the veriest sceptic that, on careful analysis of the methods described in his recent lecture, Sir JOSEPH LISTER may congratulate himself that, although he has since simplified and improved his method and has been able to do away with small increases of tension and minor irritations which were sometimes mentioned in earlier records, he from the very outset protected the patients from whom these records were taken against septic mischief, and obtained results which up to that time had never been effected in hospitals with similar classes of patients—results as good, indeed, as those now obtained in the best appointed hospitals in which the antiseptic system is in use. Most of those who have placed themselves in a position of antagonism to the antiseptic system have directed their attacks against the details of the method rather than against the principle on which it is founded. First the spray was denounced, and undoubtedly its use was attended with many serious disadvantages, not the least important of which was that it deluged the tissues laid bare by the surgeon's knife with a powerful irritant which necessarily devitalised the cells of which this tissue was composed, but in the earlier days of antiseptic surgery, when pyæmia and septicæmia, not to speak of hospital gangrene, had made their home in many of our hospital wards, Sir JOSEPH LISTER and those who were working under his guidance, believing as they did that these conditions were the result of germs which in some way or other were localised in the hospital, felt it to be a duty to guard every avenue by which such germs might make their way to either surgical or accidental wounds. Exception may be taken by some critics to minor changes of methods, but the possibility of making such changes could only be demonstrated after a more thorough knowledge of the mode of propagation of bacteria, of their life-history and ways of transmission from point to point, had been obtained. Knowing as we do now that septic material is far more frequently introduced by the finger, uncleanness, dirty instruments, or foul dressings, we must attribute ourselves that

the germs may be attacked with the least possible trouble and without the use of superfluous chemical antiseptics or too elaborate precautions, but the fact remains that we still adhere in the strictest fashion possible to the principles Sir JOSEPH LISTER enunciated even when he was carrying out his earliest experiments.

The return to the use of carbolic acid, or rather the increased use of this substance and a more perfect reliance upon its virtues as the best available antiseptic at our disposal, give remarkable evidence of Sir JOSEPH LISTER's scientific instinct (if such a term may be used), and it is now noticeable that not only in the operation theatre and in the wards have surgeons come to look upon this substance as the most convenient and reliable antiseptic for their purposes, but the most convincing corroborative evidence as to the germicidal properties of this substance has been obtained in the course of experimental investigations carried out in various laboratories, both at home and abroad.

It is scarcely necessary to point out that all the resources of antiseptic surgery have been devoted to the keeping out of micro organisms from wounds, and for this reason antiseptics whose special virtue lies in the fact that they act as such only when brought in contact with the tissues themselves or with the fluids that come from a wound are regarded with some distrust. Substances belonging to this group—iodoform, for example—may undoubtedly be of very great service where a special end is to be obtained, and it can be well understood that, where tuberculous tissue has been removed, or where old sinuses have been scraped, the actual introduction of iodoform into the wound during the earlier stages of treatment may prove of very great value, but it can scarcely be maintained that this treatment of fresh wounds by plugging with iodoform can have any advantage over the ordinary method of treatment. In fact, most people would argue that the mechanical interposition of a powder between the raw surfaces would interfere in some degree, at any rate, with the rapidity of healing, so that where the presence of micro organisms is not already suspected iodoform should not be too frequently employed.

As regards the cleansing of the skin before operations, there can be little doubt that the results obtained by those who have used carbolic acid are very different from those obtained by the German school, who rely so largely on corrosive sublimate. This latter substance, as originally pointed out by Professor KOCH himself, combines very rapidly with albuminoid material of all kinds, and in this combination becomes fixed and almost inert. Its action upon the organism depends upon its power of combining with the protoplasm of that organism, and if its "affinities," as the chemists say, in that direction are satisfied it does not go out of its way to attack any other protoplasm, so that as soon as it comes in contact with the superficial layers of the skin it unites with the protoplasm of the cell and does not make any attempt to reach the micro-organisms, which, as Sir JOSEPH LISTER points out, are so numerous in the sebaceous and other ducts. Carbolic acid is less open to objection on this score for although it does undoubtedly combine with the protoplasm it has greater penetrating power, especially as regards the fatty or sebaceous matter. It may be termed a much more searching antiseptic than bichloride of mercury and so far therefore is more trustworthy as a preparatory cleanser of the skin. This

perhaps is due in part to its extreme volatility, which property, however, is one of its chief disadvantages, a disadvantage that Sir JOSEPH LISTER has overcome by using with it his double cyanide of mercury and zinc. The double cyanide, an exceedingly insoluble substance, appears to exert a most powerful inhibitory action on the growth of micro organisms and at first sight it would appear that it might be used instead of the carbolic acid, had it not been found that, powerful as its inhibitory action is, its actual germicidal power is comparatively slight. With these two substances at command, however, all the essential properties of a good dressing are secured the carbolic acid is used to kill the germs which under various conditions might surround or come in contact with the lips of the wound, the double cyanide, in the form of a slightly soluble powder, remaining on its part to inhibit the growth of germs which might infect the saturated dressing, a function that the volatile and soluble carbolic acid cannot perform, as on account of these properties it is soon removed from the dressing.

It is curious to note that Sir JOSEPH LISTER uses the peptomising power of certain micro organisms to free his sponges from the fibrin that is deposited in their meshes, and it might be objected that those who have not Sir JOSEPH LISTER'S exact knowledge of the antiseptic properties of the various substances used, and who cannot distinguish sufficiently clearly between the mode of action of different antiseptics, can scarcely realise the importance of destroying any putrefactive micro-organisms that might remain in the sponge. If Sir JOSEPH LISTER'S methods are adhered to in their entirety, and if his principles are thoroughly mastered, there is no danger to be apprehended from the use of sponges so prepared.

From the whole of the demonstration, however, there is much comfort to be derived, for we are assured that all nature's forces are working in favour of the surgeon and his patient, the blood serum is making an effort to destroy any micro-organisms which may make their way into the wound whilst phagocytosis, as demonstrated by METCHNIKOFF, also contributes its share to the process, so that when the antiseptic precautions which should be taken by every surgeon to prevent gross septic material from making its way into the wound, or from obtaining any footing there, are taken in the case of any patient enjoying moderately good health to begin with, there should be a fair prospect of healing without the intervention of suppuration of any kind. Sir JOSEPH LISTER'S exposition of his subject is so clear, and his experiments are so definite and well thought out, as to make his position almost unassailable.

THE controversy which has recently been going on between Professor MAHAFFY of Trinity College, Dublin, and Lord Justice BOWEN on the advantages and disadvantages attending the great extension of popular education now in progress in this and other countries raises not only many incidental questions of great interest, but one fundamental problem of the highest importance—viz., how far the popularisation of education loses in depth what it gains in diffusion, how far, in other words, it sacrifices thoroughness to superficial dissemination. Must the race of scholars decay in an age when everyone is acquiring a smattering

of education? When everyone reads somehow and some thing, are none to read wisely and exhaustively? Is there any fair prospect that the universal spread of education—if that be possible—will banish poverty and reduce crime to a minimum? Is knowledge the talisman to cure the ills of society and transform human life?

These are large problems, not to be lightly dogmatised upon, and we shall confine ourselves to one phase of the controversy—viz., whether there is any incompatibility between the spread of education to all classes and the maintenance of the standards of education. Few questions are more important and no one will deny the opportuneness of the subject at the present time. We are in the full tide of an immense diffusion of popular education, be the results what they may. The operation of the English Education Act of 1871, the foundation of the Royal University and of the Intermediate System in Ireland, the vast growth of newspapers and periodical literature, the notable cheapening of books—all these and other causes have contributed to this result. It has been usual to congratulate ourselves upon this state of things as if it were pure gain, so that the somewhat Cassandra-like monitions of so experienced an authority as Professor MAHAFFY will be startling to many. His testimony is that in the area of his observation the diffusion and popularisation of education have gone hand in hand with a palpable lowering of its standards. "As regards the pupils of the higher schools in Ireland" he writes in the *Nineteenth Century*, 'it is not only my conviction, but that of many of my colleagues, that their average scholarship was higher twenty years ago than it is now. As regards classics, we are agreed that not only is the writing of verses—an excellent test of elegance—becoming almost extinct, but that prose writing is far more slovenly and inaccurate. In mathematics our new difficulty is to keep alive even an interest in its higher branches in this our famous mathematical university.' In reply to the objection that classics and mathematics are now less exhaustively studied than in a former generation because so much time is consumed on what are virtually new subjects such as French, German and Music, Professor MAHAFFY thinks the new knowledge so superficial as to invalidate the apology. Of schoolboys examined by him he says that the vast majority "had learned to translate a text-book which they could not read and to repeat grammatical rules which they could not apply. In music they had learned barren theory without any reference to practice."

We do not dispute Professor MAHAFFY'S facts, but we do demur to the interpretation put upon them. We believe that the spread of education has been on the whole a great gain, but that the gain has not been unmixed. We think that if a sufficiently wide view of the subject be taken, it will become apparent that education is undergoing a radical alteration in its purpose methods and results, and that we are at present suffering from some of the inevitable inconveniences of a transition period. Until recently education in any comprehensive sense of the term, was the privilege of the few. It was practically confined to those who had either wealth and leisure or who were prepared to face a prolonged struggle with poverty and obscurity. It had its favourite seats in secluded university towns and it shunned, rather than courted contact with the streams of commerce and industry. It became the badge of a small and exclusive caste. The

great mass of the people were either practically outside the range of its benefits, or at best received these only at second hand. All this is now being steadily altered. Universal compulsory education has widened and broadened the intellectual horizon of all classes, it has created new tastes and ambitions; it has fostered talents hitherto undeveloped. The cost of university life has been reduced, universities are more and more springing up in the large centres of industry, examination boards have been established to test the progress made by those whom the *res angusta domi* compels to study in private, university extension lectures aim at diffusing some smattering at least of university training amongst large areas of the community—in a word, education is being popularised. Pessimists sum up for us rather dolefully the result of all these efforts. They tell us that the net result has been that everybody, from the servant girl and the shop assistant to the peeress and the prince, now reads newspapers and light fiction, and that profound and accurate scholarship is disappearing from our midst. We decline to believe it. It is no doubt disappointing to find that at most of our public libraries the proportion of novels read to other books is as high as 80 and 90 per cent, but there is nothing surprising in the fact that in an age when everybody reads the general rush should be at first towards the lightest and least fatiguing form of literature. A large proportion of the readers exhaust all their available energy in their other pursuits and turn to books and periodicals simply for distraction and amusement. This is to a certain extent inevitable, still we may fairly hope that a more matured taste will tend to grow up, and that this growth will be materially helped by any measures to enlarge the—at present—very scanty leisure of the artisan classes. But if, admittedly, the great majority of readers nowadays confine themselves to the lightest forms of literature we are not prepared to grant, without further evidence, that the number of real scholars is declining. They never were, perhaps never will be, a numerous class, but if we take one test—and that perhaps the best—viz., the output of scholarly books, we think there is no reason for a despairing view of the prospects of education. Learning is no longer sunk in a well here and there. It is being universally diffused, in a perhaps shallow, but still beneficent stream. Those who look only at the shallowness of the modern stream and at the depth of the ancient wells are filled with forebodings. But we are confident that the future will prove these forebodings to have been due to a limited view of a large and complicated subject.

WE publish this week a clinical lecture on Symphysiotomy by Professor PINARD, in which he records thirteen cases of this operation performed either by himself or by his assistants in the Clinique Biodelocque during the year 1892. It is only necessary to mention the results obtained in this series of cases for it to be at once evident that the lecture is one of great interest and importance, especially to those concerned in the practice of operative midwifery. All the thirteen patients who underwent the operation recovered completely, and ten of the children were born alive, and were known to be thriving at the time when the lecture was given. In no case was the mother's power of walking impaired by the operation.

Such a record is one of remarkable success, of which Professor PINARD may be justly proud, and it can hardly fail to have an important influence on the obstetric art in other countries. If we refer to the details of the cases the evidence is for the most part as complete as could be wished that the result in each case was really due to the operation, and could not have been obtained by any other means, with equal safety to the mother. Thus in Case 2, though exact measurements are not given, we find that the pelvis was flattened, as the sacral promontory was accessible, two attempts were made to deliver by the forceps under chloroform without success, symphysiotomy was then performed, and a living child was easily extracted by the forceps. The child weighed over 10 lb and was twenty inches and a half in length. In several other cases previous confinements had only been terminated by basiotripsy. Subsequently, however, by means of symphysiotomy these patients were delivered of living children. Yet symphysiotomy is not a new operation—it is indeed an older operation than ovariotomy. At all events, the first symphysiotomy was performed by SIGAULT and LEROY in 1777, whereas the first ovariotomy is generally considered to have been McDOWELL's case in 1809. Some points of similarity may be observed in the history of symphysiotomy and ovariotomy respectively. Thus both operations had become almost obsolete during the first half of the present century. As regards symphysiotomy, HARRIS's table records seventy cases from 1777 down to 1858, with a maternal mortality of 37 per cent and a foetal mortality of 67 per cent. It is worth noticing that the last ten of these seventy cases were performed between 1836 and 1858 and show a maternal and a foetal mortality of 50 per cent. A table of fifty cases, from 1866 to 1880, chiefly by Professors MORISANI and NOVI of Naples, shows a maternal mortality reduced to 20 per cent and a foetal mortality of 18 per cent. If we look at the results of symphysiotomy since 1880 it seems to be the fact that on the Continent the operation has attained to the assured position that has long since been everywhere accorded to ovariotomy, and that it involves little or no risk to the mother. It cannot now be disputed that the space available for the passage of the foetus is serviceably increased by symphysiotomy performed on a woman *in labour*. Those who formerly maintained the contrary were misled by post-mortem observations made on the bodies of those who had not died during pregnancy or labour, or if on the bodies of those who had died in childbirth, the observations were made too long after death, for even two or three days have been found to make a remarkable difference in this respect. When the pubic bones are separated to the extent of six centimetres it has been shown that lines drawn from the sacral promontory to the ends of these bones are increased about fifteen millimetres. The gap so formed allows a projection of the foetal head beyond the bony ring of the pelvis. The gain thus obtained has been estimated as equivalent to an additional seven millimetres, making a total increase of twenty-two millimetres, or rather more than three quarters of an inch. The transverse and oblique diameters of the pelvis are also necessarily increased. Considerations based on these figures, and on the measurements of the foetal head at term, go to show that symphysiotomy is available at term in a simple flat pelvis.

having a conjugata vera of about 2½ in., or perhaps a trifle less (in the table of fifty cases already referred to there are two cases where the conjugata vera is given as 2⅔ in., in both the result was satisfactory in the case of both mother and child) It seems clear, however, that some at least of the fatality formerly attending the operation must be ascribed to its having been performed in unsuitable cases—cases where there was extreme contraction. Thus in SIGAULT's last operation (1778), which was fatal to both mother and child, the conjugate only measured about twenty three lines, and other similar instances might be cited. In this case the operation seems to have been undertaken with the deliberate object of substituting symphysiotomy for Cæsarean section, even in the highest degrees of pelvic contraction. That such a position is untenable is shown both by the excessive mortality attending such cases as well as by the researches of recent times that have been undertaken with a view to placing the operation on a rational rather than on an empirical basis. It would be premature, especially on the part of any English writer, to attempt to define exactly within what limits symphysiotomy may be expected to prove useful. One thing, however, is clear—namely, that the operation is preëminently suitable for those cases where the pelvis is just too small to allow of the delivery of a living child, and for those where the induction of premature labour with difficulty succeeds in bringing about the birth of a living child, even with the aid of instrumental assistance. The mortality amongst such of these children as are born alive is extremely high, as every obstetrician knows. It seems precisely in this group of cases that we may look for good results from modern symphysiotomy. It is a remarkable thing that so far as we know the operation has only once been performed in England, and that unsuccessfully, more than 110 years ago. The case was one where the pelvis was deformed in a high degree by osteomalacia, and the conjugata vera was only two and a quarter inches. The woman had been left a long time in labour, and the fœtus was putrid. Such a degree of contraction was of course too great for the case to be a proper one for symphysiotomy, moreover the fact of the patient having been a long time in labour and the fœtus being putrid made the case a very unsuitable one to serve as a test of the value of a new operation. Probably modern successes have been chiefly due to two things—the avoidance of the operation in cases of extreme contraction, and a strict observance of antiseptic methods. Unless English obstetricians are unable to obtain results similar to those reported from Italy and France, which we are unwilling to believe, they will, except in the rarest instances, be spared the painful alternative of either performing craniotomy on a living child, or of subjecting the mother to the risk of the Cæsarean section—an operation that, when all has been said, still remains one of considerable danger.

DR HUGH JAMESON, Resident Surgeon of the British Hospital, Monte Video, has had the degree of Doctor of Medicine and Surgery conferred upon him by the Monte Video Faculty of Medicine. This proceeding is unique, the usual practice in that territory being to recognise the diplomas which the medical man already bears.

Annotations.

"Ne quid nimis."

THE HUNTERIAN ORATION

SELDOM indeed has an audience more representative or distinguished met within the walls of the Royal College of Surgeons than that which assembled on Tuesday last—the centenary of the death of the famous investigator, biologist and surgeon, John Hunter—to listen to the Hunterian Oration delivered by Mr Thomas Bryant, the President of the College. The audience was honoured by the presence of His Royal Highness the Prince of Wales and of his son, His Royal Highness the Duke of York. It is about fifteen years since the Prince of Wales—who on that occasion was accompanied by Mr Gladstone—visited the Royal College of Surgeons to hear Sir James Paget deliver the Hunterian Oration, and the alumni of the College have good reason to re-echo the President's expression of their great appreciation of the honour which has been conferred upon it by this visit of their Royal Highnesses. The surroundings were very striking. The orator, in his robes of office, stood at the table, on which was placed a small timepiece which had belonged to John Hunter, which Mr Bryant assured his audience "goes well and keeps good time yet." Over his head hung the famous picture by Sir Joshua Reynolds of the man to honour whose memory they had that day assembled. The portrait is well known and somewhat dimmed in colour, but, as the rays of the setting winter sun glanced on the picture, the thoughtful, upturned eyes and general expression of quiet yet acute observation, seemed to cause the picture to glow with memories and associations. These appeared to become even more real as the orator detailed in his masterly oration the facts of Hunter's industry as a worker, of his transcendent capacity for taking trouble, of his humility, of his career as a seeker after truth, and of his work as surgeon. As a literary effort it is difficult to speak of the oration in terms of praise too high for such a masterpiece of industry and research and of arrangement, which gave new life to old facts and new interest to old theories. We feel assured that no one left the College of Surgeons on Tuesday without a stimulus to fresh industry, or, to use the orator's own words, "without a powerful incentive to continued good work." The portion of the oration dealing with the treatment of diseases by stimulants was peculiarly interesting, as were the observations on cancer and the quotation concerning Hunter's radical method of preventing hydrophobia. Mr Bryant concluded with the remark that the seeds of science which Hunter had sown possessed a germinal principle of life which guaranteed vitality. Their Royal Highnesses, before leaving, were conducted through the museum, accompanied by the President and Professor Stewart, the conservator of the museum.

THE SUPERINTENDENT OF STATISTICS

THE announcement of Dr Ogle's resignation of the post which he occupies in the department of the Registrar of Births and Deaths points to a vacancy in the immediate future which has great interest for the medical profession. Dr Farr gave to the post in question a distinctively medical character, and the reports which he issued as a medical statistician had a wide influence in educating the public to appreciate the value and significance of vital statistics in their relation to public health. Dr Ogle has not failed to maintain the standard of merit thus set, and the introductory chapters to the Registrar General's annual reports are known to have been largely drawn up by him. The selection of his successor is, under these circumstances, a matter of great importance both to the public and to the medical profession. Fortunately candidates are not wanting

who would do honour to the post. One is Dr Arthur White legge, who now occupies the position of medical officer of health to the West Riding of Yorkshire. He is also examiner in Public Health to the University of London, Milroy Lecturer to the Royal College of Physicians and author of a standard work on Hygiene, and most of his well known contributions to medical literature, including a paper on Measles which he recently read before the Epidemiological Society, show that he has a complete grasp of the value and bearing of statistics in relation to medicine. Dr John Tatham, the well known medical officer of health for Manchester, is also a candidate for the post. As an administrator Dr Tatham has done work beyond his fellows, and no one can read the excellent series of reports which he has issued on the health both of Salford and of Manchester without seeing that he has made vital statistics a constant and careful study. His recent Life Table for Manchester is also a piece of work of distinct statistical merit. Dr Newsholme, medical officer of health for Brighton, is also a candidate. His career at the London University was a distinguished one, and he is the author of a work on Vital Statistics which has considerable merits and which is much used by medical officers of health. Although the General Registrar Office is regarded as a department working in connexion with the Local Government Board, it is somewhat curious that the office of Superintendent of Statistics which is now in question is not in the gift of the President of that Board, but of the First Lord of the Treasury. It is, however, to be hoped that in filling the vacancy it will be borne in mind that the relationship existing between it and the public health service of the country is a close and intimate one, and that it is important that this relationship should be maintained and even rendered more intimate.

INSPECTION OF PREMISES OCCUPIED BY OUT- WORKERS IN CERTAIN TRADES

By the Factory and Workshop Act, 1891, it was enacted that the sanitary regulations affecting workshops should be placed under the direct control of the Sanitary Authority instead of that of the inspector of factories. The Act of 1891 was framed after the publication of the report of the Sweating Commission, and was intended to correct some of the grave abuses which the inquiry brought to light. By the Act of 1878 it was held that a place solely used as a dwelling shall not be deemed to form part of a workshop. It was precisely in the dwellings of the outworkers, however, that the worst evils of sweating existed. By Section 31 of the new Act it is provided that with the exception of rooms used solely for the purpose of sleeping, a dwelling shall be deemed to form part of a workshop. It is evident therefore, that by making the local authority responsible for the hygiene of workshops in their district powerful means have been placed in their hands for the improvement of the condition of the outworkers, although it is to be regretted that exception should have been made in the case of sleeping rooms for the purposes of the Act. On Nov 19th, 1892, a circular letter was addressed by the Local Government Board to the various sanitary authorities and we have been kindly favoured by Dr F J Waldo, the medical officer of health for the parish of St. George the Martyr, Southwark, with a copy of the report which he submitted to the vestry at the request of the Public Health Committee in reference to this letter. We are informed that the order requires the occupier of every factory and workshop, and every contractor employed by any such occupier in any of the following businesses, to keep lists of outworkers according to a prescribed form—viz., (1) the manufacture of articles of wearing apparel, (2) cabinet and furniture making and upholstery work, (3) the manufacture of electro plate, and (4) the manufacture of files. These lists are to be open to the inspection of the inspector of

factories or any officer of the sanitary authority. The medical officer of health and sanitary inspectors are particularly requested to examine these lists from time to time in order to familiarise themselves with places in which outworkers are employed and thus the more readily to correct existing evils. As Dr Waldo very rightly points out, power is thus conferred upon the sanitary officials of penetrating into the dens inhabited by some of the outworkers and of improving their hygienic surroundings. It would have been better, however, had no restriction been imposed by the Act in the definition of "workshop," so that every portion of the house might have been open to the inspection of the medical officer of health and his staff. By the recent Order further facilities will be placed in the hands of sanitary authorities for checking the spread of infectious disease, now but too frequently conveyed by wearing apparel and upholstery. It would appear that occupiers of the scheduled businesses have already evinced their readiness to coöperate with the Public Health authority, and although not required to forward lists of outworkers to the sanitary authority have all expressed to Dr Waldo their willingness to do so. It is clear, however, that although the factory may be situated in a certain district all the hands need not reside in that district. Indeed, many of them may live far afield. Consequently, unless some system of coöperation be instituted amongst sanitary authorities only a proportion of outworkers will be brought under supervision. Dr Waldo suggests two methods by which the difficulty may be overcome (1) "The coöperation—if possible in so unwieldy a city as administrative London—between the various sanitary authorities, so that the officer appointed in each district shall inspect the lists of workers in that district, and extract from those lists, and furnish to other metropolitan districts, a copy of all the necessary particulars regarding outworkers working outside his district," or (2) the more simple and efficacious plan—viz., "the organisation under the Home Secretary of a staff of inspectors with a chief whose duty it will be to inspect all the lists of outworkers and to exact from each metropolitan sanitary authority the requisite detail, and forward the same to the various medical officers of health." We are informed that the latter method has been adopted by the Home Secretary, so that we may hope that the organised system of inspection to which outworkers in the scheduled businesses will be subjected in the future may result in healthier homes and less over pressure.

THE NURSING OF CHOLERA PATIENTS

A CIRCULAR has been issued by the Special Committee of the Royal British Nurses' Association calling the attention of the various nursing associations throughout the country to the fact that in September last (as announced in THE LANCET of Aug 27th) a roll for nurses who would hold themselves prepared to attend in cases of cholera was opened by the Association. The action of that body in this regard was due to a suggestion made by the Princess Christian, and the appeal which her Royal Highness addressed to the nurses of Great Britain at the time elicited a prompt and favourable response. The Special Committee is intended to act as a central means of communication to which the constituted authorities can apply in times of emergency with some certainty of securing ready assistance, though it is not to be allowed to interfere with the financial arrangements or independence of any of the existing nursing institutions or agencies. Accompanying the circular are papers relating to the employment of nurses and suggestions for their guidance which have received the approval of competent authorities. The Special Committee are, we are informed, desirous of ascertaining the number of nurses whose services may be relied upon in the event of cholera prevailing in this country in the ensuing summer. In connexion with this subject it may

be mentioned that the second lecture of the session of the Royal British Nurses' Association will be held to-day (Friday) at 8 P.M., when Miss Annesley Kenealey will lecture on "Cholera Nursing."

AN INTERESTING RELIC

AFTER the delivery of the Hunterian Oration by Mr Thomas Bryant, the President of the Royal College of Surgeons, Dr Samuel Lee of St Leonards-on-Sea presented to the College the hair of the distinguished physician and physiologist, Dr William Hunter, F.R.S., brother of the celebrated John Hunter, which was left to the late Dr Robert Lee by Mr William Hunter Baillie in 1861.

THE DANGER OF WOODEN HOSPITALS

At a moment when so many sanitary authorities are hurriedly trying to make amends for past failure to provide their districts with isolation hospitals by running up temporary buildings there comes a serious warning from Kidderminster and from the other side of the Atlantic as to wooden buildings. At the County Lunatic Asylum, Dover, New Hampshire, a terrible fire broke out and no less than twenty-four lives were sacrificed. At Kidderminster the same catastrophe occurred, but happily the actual loss of life was limited to one patient, although the building was utterly destroyed. The most common practice at present in operation as regards temporary hospitals in this country is to build them of corrugated iron, but these buildings are as a rule lined throughout—floor, walls and ceiling—with wood, and hence they present a similar, though doubtless a much modified, source of danger. The warnings received will, we trust, conduce to a more general erection by sanitary authorities of properly constructed permanent buildings.

THE SALE OF PROPRIETARY MEDICINES CONTAINING POISONS

SOME time since the Pharmaceutical Society was congratulated upon having obtained an important decision respecting the sale of chlorodyne. Before a county court judge the Society was awarded a favourable decision in an action for penalties under the Pharmacy Act, 1868 the defendants being grocers, not chemists (would not the word "druggists" be more accurate in this respect?) who had sold chlorodyne. On appeal, before Mr Justice Lawrance and Mr Justice Collins, the Court upheld the decision of the county court judge, that the appellants not being chemists and selling chlorodyne were liable to penalties. The arguments used by counsel and the terms in which the judgment was delivered are alike of interest, even though it may be feared that a final solution has not yet been reached as the Court gave leave to appeal. The counsel for the defendants argued that, although chlorodyne was said to contain two grains of morphine to the fluid ounce, it was not a poison in the ordinary sense of the word, but if it was it came within the exemption of the section relating to "patent medicines." On behalf of the Society, Mr Poland urged that the Legislature had divided poisons into two classes—first, a class of more active and deadly poisons, which could only be sold by the chemist to someone known to him or introduced by someone who is known, and a second class, again only to be sold by chemists if the vessels containing them were labelled poison. Inasmuch as chlorodyne contained a 'preparation of opium or of poppies' he considered that it came within the second class and he denied that it was a patent medicine. Mr Justice Lawrance, in giving his decision said that he felt that the simple question to be decided was whether a person, not a chemist, could sell a proprietary medicine containing a poison, and, after some doubt, he had come to the conclusion that such a person could not do so. The idea of exemption as a

patent medicine was easily swept aside, and, for the present at least, it was ruled that if a medicine contained a poison mentioned in the schedule, that medicine ought to be labeled. As notice of appeal has been given, any detailed criticism of the merits of the case must be reserved. It may be sufficient to remind our readers of the frequency of fatalities from overdoses of chlorodyne, taken, presumably, in ignorance, and of the many occasions upon which this action of the Pharmaceutical Society has been urged by strong representations from coroners' juries. Meanwhile, whatever the final stage may be, it is impossible not to feel that this inquiry and this ventilation of the possible dangers of chlorodyne may work for good in limiting the reckless employment of this compound, whether it be a "patent medicine" or not.

AN IRREGULAR DEATH CERTIFICATE

MR. A. BRAXTON HICKS recently held an inquiry into the death of Richard Kullick, aged sixty, a master shoemaker, who had been attended till Jan. 24th by Mr Freeman, of 203, Blackfriars road, his club doctor. Thereafter he was attended by Mr Freeman's assistant, who had been known to the deceased's family as "Dr" Park, but who was unqualified. The certificate was in the handwriting of "Dr" Park, but was signed by Mr Freeman, and stated that he had seen the deceased on the 29th, that is five days after his last visit and two before the patient's death. He explained this at the inquest on the ground that when he signed the certificate he thought he had seen the deceased on the 29th. The jury condemned the action of the medical man.

THE MULTIPLICATION OF SPECIAL SOCIETIES

WE are threatened with another deluge—a deluge of special societies. One by one they multiply, and no man can say where they will stop. There is, we believe, already a Laryngological and Rhinological Society, though we have felt compelled to refuse the recognition of its separate existence, and we are now threatened with another—the Laryngological Society of London. The menace is not the less serious, but much the more so because the first list of names, beginning with that of Sir George Johnson, includes a large number of others whose authority in medicine and surgery generally we all cheerfully recognise. We really feel that this is an evil to be repressed. If we are to have a Laryngological Society, why not a Pharyngological Society and a Rectal Society, or to be still more particular, one society for fistula and another for cancer of the rectum. The gentlemen whose names are in this list and who give it weight are men whose reputation in medicine or surgery is broad and general. Take Sir George Johnson as an illustration. It has long been known that he though having a highly specialised knowledge of momentous organs, has taken special interest in diseases of the throat, in cholera, in diphtheria, and has shown himself to be familiar with disease in every department of medicine. We are sure that such a physician of the whole body will be proof against any tendency to take a narrow or specialistic view of any disease of one of its parts—a tendency which has brought great discredit on the profession and threatens to bring much more. Why should Sir George Johnson give his high sanction to a special society for the consideration of diseases of the larynx? Is there any conceivable reason for creating a society for such exclusive work that might not be urged with tenfold force in favour of the creation of a Nephrological Society? Life and time are very limited quantities. Neither students nor medical men have the leisure to go to an unlimited number of societies or hospitals. If every particle of mucous or serous membrane is to have its own special society and hospital it can only be at the expense of the general medical societies and the great general hospitals. This multiplication of societies is an evil as is that of hospitals.

It is to be counteracted by bringing special diseases to notice in the general societies and in the general hospitals, where they may be seen by students and general practitioners, who in their turn will be induced to cultivate the use of special methods and instruments. We have no faith in the specialism that is not, like Sir George Johnson's, evolved out of general experience and knowledge of the body. Such evolution is retarded rather than helped by special and close societies. We have abstained from using arguments against special societies and hospitals originating in a lower set of motives, as having no application to the gentlemen whose names are before us and who seem ready to become responsible for the creation of another 'superfluous' society. We prefer to base our objections on more general and higher grounds, and appeal to these very gentlemen to help us in averting the deluge.

THE LONDON WATER-SUPPLY

THE Royal Commission of Metropolitan Water supply resumed its sittings on Monday last and the hearing of evidence was concluded on Wednesday. Mr J H Shoveller of the Registrar General's office gave particulars as to the extent of the existing supply, and he dealt also with the probable growth of population. He was followed by Mr W J Dibdin, chemist to the London County Council, and other expert analysts, amongst whom was Dr Frankland, who gave evidence in regard to the quality of the present supply. Dr Frankland suggested in certain cases a system of double filtration. His verdict was that the quality of London water, on the whole, was very good and occasionally—on rare occasions—very bad. In the latter case it was because of the admission of flood water into the reservoirs. Therefore, on no pretext whatever, as we have urged all along, should the filtering process be allowed to become defective in the least degree. It might happen—who can tell?—that at the very time when the beds were being repaired, or were found to be unsatisfactory in some particular, contaminated water was passing through to the mains. The community should never be exposed to such a risk. At the last sitting of the Committee, on Wednesday, Mr A R Bunney and Major General de Courcy Scott, R.E., Water Examiner under the Metropolitan Water Act of 1871, also gave evidence.

TWO CASES OF CÆSAREAN SECTION

THIS somewhat unusual operation has recently been performed at two of our large London hospitals, St Thomas's Hospital and the London Hospital, by the obstetric physicians attached to them. We consider that the operators exhibited a right and just regard for the instruction of the students of the schools in which they are teachers by removing the patients to the hospitals named rather than in operating at the York road Lying in Hospital, to which they are also attached, and at which the patients first applied for aid. Amongst the large number of students who were present there were possibly some who may be called upon to act in similar cases, and it is not improbable that the details of the operations as witnessed respectively on the 8th and 9th inst will be remembered and will give the necessary confidence and knowledge to enable them to save lives. On Wednesday, the 8th inst., Dr Herman operated at the London Hospital. The case was one of extreme rickety deformity. Labour had come on at the end of the eighth month of pregnancy and the liquor amnii had escaped. The uterus was opened while within the abdomen and pressed out of the wound after the child had been extracted. The uterine wound was closed with eight interrupted silk sutures, passing through the muscle but not through the decidua, and a fine continuous catgut suture of the peritoneum. The child was living, and at the date of our last report (Feb 14th)

both mother and child were doing well in every respect. In order to sterilise the patient both Fallopian tubes were tied. A loop of one was tied and cut off, the outer half of the other was ligatured and removed. The second operation was performed at St. Thomas's Hospital by Dr Cullingworth on Feb 9th on a patient aged thirty-one, suffering from rickety pelvis, with an estimated conjugate diameter of 2½ inches, and pregnant for the seventh time. Three of her previous pregnancies had terminated in miscarriage and one in labour at term, when craniotomy had to be performed. On two occasions labour had been induced at seven months, the first time the child lived a few hours, the second time the patient was in the General Lying in Hospital in York road, where delivery was effected by version, followed by perforation of the after coming head. On again becoming pregnant she was advised to go to full time and be delivered by Cæsarean section. To this she eventually consented. The operation was performed a few days before labour was expected. Labour had not commenced. The uterus was opened *in situ* and the child extracted before the liquor amnii had been allowed to escape. The child, a well formed male, 7½ lb in weight, cried vigorously as soon as it was born. The placenta and membranes were quickly removed. There was a little delay owing to the uterus not contracting well, but the amount of blood lost was not very great. No elastic ligature was used. The outer inch of both Fallopian tubes was removed in Dr Cullingworth's case, as this had been proved to be necessary by a case which occurred four weeks ago at Guy's Hospital, and which showed that mere ligature is insufficient when they are simply ligatured in continuity. The uterine wound was secured by six deep and about as many half-deep silk sutures. The operation lasted fifty five minutes. Except that the patient vomited for a few hours during the latter part of the second day her recovery has been as satisfactory as if after a normal confinement, the highest temperature having been 99.4°.

THE PHENYL-HYDRAZINE TEST AND SUGAR IN NORMAL URINE

IN the course of a paper read on Tuesday evening at a meeting of the Royal Medical and Chirurgical Society on the disputed question as to whether sugar is ever present in normal human urine, Mr G Stillingfleet Johnson, F.R.S., gave a demonstration of the above test for sugar, by which its presence in quantities of much less than a tenth of a grain per ounce can be shown with certainty. The process is as follows. The urine is completely precipitated with lead acetate and filtered. The filtrate is rendered alkaline with potash, and a solution of phenyl hydrazine is added. The mixture is well shaken and boiled. An orange colour is developed, which is followed by an orange precipitate, when excess of acetic acid is added if sugar be present. The clinical value of the test is increased by its not being affected by excess of urates or kreatinin, which occasionally lead to error in inexperienced hands when testing human urine for sugar with either cupric salts or picric acid in boiling alkaline solutions. Dr Curnow stated that he had used the phenyl hydrazine test with complete satisfaction for the past two or three months. The test was discovered by Fischer and made better known by C Schwartz. It precipitates aldehydes and ketones, glucose belonging to the former class. It is almost impossible to imagine that any other aldehyde or any ketone but glucose can become a constituent of normal urine, and hence the peculiar value of the reagent. There are other carbohydrates if not glucose among the extractives in normal human urine, and the question as to whether glucose is amongst them in a very minute proportion seems to rest on the relative value of the benzoyl chloride test advocated by Dr Hunter and the phenyl hydrazine test used by Mr Stillingfleet Johnson.

If the entire reducing action of the normal urine can be accounted for by the uric acid and kreatinin which it contains, as is so positively stated by Mr Johnson, it is clear that there is no room for believing that glucose or any other carbo-hydrate with a "reducing" action can be present in normal urine. Phenyl hydrazine is a derivative from phenol.

CHOLERA SURVEY

THE general visitation of port sanitary districts in anticipation of the recrudescence of cholera during the present year is now in full working order, and the medical inspectors of the Local Government Board are actively engaged in the duties on several portions of the coast. Thus we hear of Mr T W Thompson in Northumberland ports, of Dr Copeman at Great Yarmouth, of Dr Theodore Thomson at Cowes and Portsmouth and of Dr Bulstrode at Poole and Falmouth. Inspection of riparian districts will follow that in the port districts, and, as in 1884-86, a number of urban and rural inland districts will need special visits with view to such action as will tend to free them from risk in case of the importation of cholera.

THE NEED OF MEDICAL EVIDENCE IN CASES OF ALLEGED INSANITY

OUR attention was recently directed to a curious anomaly in certain legal proceedings at the Cape, an account of which we published in a letter from Dr Cartwright Reed in our issue of Jan. 21st, at page 167. The writer had up to the occurrence of the case which he records been under the impression that "no person could be pronounced of 'unsound mind' without the support of medical testimony." He doubts whether any British jury would venture to return such a verdict unless it was supported by expert evidence. It cannot but be regarded as a most unsatisfactory proceeding that any person should be adjudged to be insane without the support of medical testimony. That a British jury has power, even in a criminal case, to return a verdict of "Guilty of the act, but insane at the time it was committed," without medical evidence is shown in the case of the Rev Henry J Dodwell, who was tried before the late Baron Huddleston in March, 1878, for "assault" after firing a pistol at the then Master of the Rolls, Sir George Jessel. Mr Dodwell was ordered to be detained during Her Majesty's pleasure as a criminal lunatic. We are strongly of opinion that cases where the existence of insanity is alleged ought never to be decided without medical evidence.

THE DIFFUSION OF SMALL-POX

THE diffusion of small pox still continues and there seems to be no diminution in the number of places attacked, but, on the other hand, no new outbreaks of any considerable dimensions are reported, and in most of the towns in which a rapid increase seemed imminent there has been a distinct reduction in the number of fresh attacks. It is as yet too early to speak with any confidence as to the prospects for this spring, but it is quite possible that next winter and spring may be for us the most serious point of the present prevalence, and not the next few months. If once we can tide over the month of May our anxiety as to an epidemic on a wide scale for this year may be at an end. There is, however, still time for a wide prevalence during the three months which have yet to elapse. Amongst the places as to which fresh news comes to hand we note the following: Aston Manor, Barnard Castle, Bedford, Birmingham, Blackburn, Bradford, Bromyard, Bury, Carlisle, Chadderton, Cogan, Crewe, Derby Densport, Dover, Exeter, Enfield, Failsworth, Guildford, Halford, Huddersfield, Jarrow, Ledbury, Leeds, Leicester (where the new attacks last week were only six in number), Liverpool, Liversedge, Macclesfield, Manchester, Middlesbrough, New-castle-on Tyne, Nottingham, Oldham (where fifteen fresh

attacks have occurred during the past week), Preston, Rotherham, Runcorn, St Helen's, Salford, Sheffield, South Shields, Stalybridge, Southampton, South Stoneham, Stockport, Spennymoor, Shrewsbury, Sunderland, Swansea, Wakefield, Warrington, Warwick, Wigan, Widnes, Wolverhampton, Yeadon and York. In the metropolis the disease continues slowly to extend. There were 109 cases of small pox on board the hospital ships on the 13th inst, in addition to a few cases at Highgate.

MR GLADSTONE'S SPEECH

WE must leave to politicians the appraisement of Mr Gladstone's speech on Monday, regarded as a piece of statesmanship, but regarded from a medical or physiological point of view there can be no difference of opinion. The performance must be regarded and must remain not only as historical, but probably as unique in the history of eloquence and of States. Those who were privileged to be amongst the audience will never forget the scene or the speaker. In the crowded chamber, filled with all that was distinguished and influential in British society, his voice was heard for the first hour of the speech with perfect ease, and even when its physical force began to abate it was still felt as an influence altogether exquisite and refined. No difference of opinion could avail to save the listener from the spell of a voice, always seconded by the choicest amenity of expression, which it may safely be said has no rival in contemporaneous Parliaments. The wonder of all this is doubled by the fact that the speaker is in his eighty-fourth year. Though there was a perceptible falling off in the force and volume of voice as the second hour was reached, the animation of the orator was all intact. His eye, and especially his right hand brought into emphatic contact with the table from time to time, testified to the vehemence of his thought and feeling, and when occasion required it, as for the delivery of a passage of special importance or the final peroration a reserve of voice was again and again drawn upon, and the enthusiasm of the mighty audience swelled the effect of the eloquence by which it was itself swayed. The most marvellous part of all was to see the orator after he had resumed his seat looking as serene as if nothing unusual had been done, and to learn that he went home to dine quietly with his family and to sleep with as little disturbance as if he had only been engaged in the most ordinary occupation. The record of eloquence is beaten by our octogenarian Premier, and, apart from any consideration of politics, with which we are not concerned, we are all very proud of him.

CHOLERA AND ALIEN IMMIGRATION

THE question of alien immigration has been brought prominently before the country by means of Mr James Lowther's amendment on the Address, but it is clear that the Government are not prepared to put a stop to it or even to that portion of it which can be properly styled "destitute." Some stimulus in the direction aimed at by Mr Lowther has evidently been brought about by the attitude adopted by the Local Government Board in their amended Cholera Order, but it should be made clear that this Order only professes to deal with a public health question and not with one that has to do with foreign labour or imported pauperism. The immigration last autumn of expelled Russian Jews into this country *via* Hamburg constituted a danger to public health not because they were poor and alien, but because they were unable to give that guarantee as to some definite address to which they were going and where they could be kept under supervision by the local health officer during the incubation period of cholera. Hence when passengers from infected ports are "filthy or otherwise unwholesome," or when they are unable to satisfy the port medical officer of health as to their names, places of

It is to be counteracted by bringing special diseases to notice in the general societies and in the general hospitals, where they may be seen by students and general practitioners, who in their turn will be induced to cultivate the use of special methods and instruments. We have no faith in the specialism that is not, like Sir George Johnson's, evolved out of general experience and knowledge of the body. Such evolution is retarded rather than helped by special and close societies. We have abstained from using arguments against special societies and hospitals originating in a lower set of motives, as having no application to the gentlemen whose names are before us and who seem ready to become responsible for the creation of another 'superfluous society.' We prefer to base our objections on more general and higher grounds, and appeal to these very gentlemen to help us in averting the deluge.

THE LONDON WATER-SUPPLY

THE Royal Commission of Metropolitan Water supply resumed its sittings on Monday last and the hearing of evidence was concluded on Wednesday. Mr J H Shoveller of the Registrar General's office gave particulars as to the extent of the existing supply, and he dealt also with the probable growth of population. He was followed by Mr W J Dibdin, chemist to the London County Council, and other expert analysts, amongst whom was Dr Frankland, who gave evidence in regard to the quality of the present supply. Dr Frankland suggested in certain cases a system of double filtration. His verdict was that the quality of London water, on the whole, was very good and occasionally—on rare occasions—very bad. In the latter case it was because of the admission of flood water into the reservoirs. Therefore, on no pretext whatever, as we have urged all along, should the filtering process be allowed to become defective in the least degree. It might happen—who can tell?—that at the very time when the beds were being repaired, or were found to be unsatisfactory in some particular, contaminated water was passing through to the mains. The community should never be exposed to such a risk. At the last sitting of the Committee, on Wednesday, Mr A. R. Binney and Major General de Courcy Scott, R.E., Water Examiner under the Metropolitan Water Act of 1871, also gave evidence.

TWO CASES OF CÆSAREAN SECTION

THIS somewhat unusual operation has recently been performed at two of our large London hospitals, St Thomas's Hospital and the London Hospital, by the obstetric physicians attached to them. We consider that the operators exhibited a right and just regard for the instruction of the students of the schools in which they are teachers by removing the patients to the hospitals named rather than in operating at the York road Lying in Hospital, to which they are also attached, and at which the patients first applied for aid. Amongst the large number of students who were present there were possibly some who may be called upon to act in similar cases, and it is not improbable that the details of the operations as witnessed respectively on the 8th and 9th inst will be remembered and will give the necessary confidence and knowledge to enable them to save lives. On Wednesday, the 8th inst., Dr Herman operated at the London Hospital. The case was one of extreme rickety deformity. Labour had come on at the end of the eighth month of pregnancy and the liquor amnii had escaped. The uterus was opened while within the abdomen and pressed out of the wound after the child had been extracted. The uterine wound was closed with eight interrupted silk sutures, passing through the muscle but not through the decidua, and a fine continuous catgut suture of the peritoneum. The child was living, and at the date of our last report (Feb 14th)

both mother and child were doing well in every respect. In order to sterilise the patient both Fallopian tubes were tied. A loop of one was tied and cut off, the other half of the other was ligatured and removed. The second operation was performed at St. Thomas's Hospital by Dr Cullingworth on Feb 9th on a patient aged thirty one, suffering from rickety pelvis, with an estimated conjugate diameter of 2½ inches, and pregnant for the seventh time. Three of her previous pregnancies had terminated in miscarriage and one in labour at term, when craniotomy had to be performed. On two occasions labour had been induced at seven months, the first time the child lived a few hours, the second time the patient was in the General Lying in Hospital in York road, where delivery was effected by version, followed by perforation of the after coming head. On again becoming pregnant she was advised to go to full time and be delivered by Cæsarean section. To this she eventually consented. The operation was performed a few days before labour was expected. Labour had not commenced. The uterus was opened *in situ* and the child extracted before the liquor amnii had been allowed to escape. The child, a well formed male, 7½ lb in weight, cried vigorously as soon as it was born. The placenta and membranes were quickly removed. There was a little delay owing to the uterus not contracting well, but the amount of blood lost was not very great. No elastic ligature was used. The outer inch of both Fallopian tubes was removed in Dr Cullingworth's case, as this had been proved to be necessary by a case which occurred four weeks ago at Guy's Hospital, and which showed that mere ligature is insufficient when they are simply ligatured in continuity. The uterine wound was secured by six deep and about as many half-deep silk sutures. The operation lasted fifty five minutes. Except that the patient vomited for a few hours during the latter part of the second day her recovery has been as satisfactory as if after a normal confinement, the highest temperature having been 99.4°.

THE PHENYL-HYDRAZINE TEST AND SUGAR IN NORMAL URINE

IN the course of a paper read on Tuesday evening at a meeting of the Royal Medical and Chirurgical Society on the disputed question as to whether sugar is ever present in normal human urine, Mr G Stillingfleet Johnson, F.C.S., gave a demonstration of the above test for sugar, by which its presence in quantities of much less than a tenth of a grain per ounce can be shown with certainty. The process is as follows. The urine is completely precipitated with lead acetate and filtered. The filtrate is rendered alkaline with potash, and a solution of phenyl hydrazine is added. The mixture is well shaken and boiled. An orange colour is developed, which is followed by an orange precipitate, when excess of acetic acid is added if sugar be present. The clinical value of the test is increased by its not being affected by excess of urates or kreatinin, which occasionally lead to error in inexperienced hands when testing human urine for sugar with either cupric salts or picric acid in boiling alkaline solutions. Dr Curnow stated that he had used the phenyl hydrazine test with complete satisfaction for the past two or three months. The test was discovered by Fischer and made better known by C Schwartz. It precipitates aldehydes and ketones, glucose belonging to the former class. It is almost impossible to imagine that any other aldehyde or any ketone but glucose can become a constituent of normal urine, and hence the peculiar value of the reagent. There are other carbohydrates if not glucose among the extractives in normal human urine, and the question as to whether glucose is amongst them in a very minute proportion seems to rest on the relative value of the benzoyl chloride test advocated by Dr Hunter and the phenyl hydrazine test used by Mr Stillingfleet Johnson.

Pharmacology and Therapeutics.

TOXIC EFFECTS OF BARIUM SALTS.

It has been known for some considerable time that if salts of barium are given in large doses toxic effects are produced. Cases of poisoning of human beings by these salts are, however, extremely rare. Nevertheless as the therapeutic value of the compounds of barium has been more fully recognised lately than formerly, it is important to ascertain what the poisonous symptoms of large doses of such salts are, and with this object Drs. Pilbet and Malbecq have made a series of experiments on animals. Chloride of barium was administered subcutaneously in doses corresponding to a centigramme for every kilogramme of body weight of the animal experimented on. With such doses death occurred within twenty-four hours in dogs, with less powerful doses the animals lived longer, but in all cases toxic phenomena presented themselves. These consisted of persistent vomiting, diarrhoea, albuminuria and hæmoglobinuria, and convulsions followed by rigidity. After death various lesions were found in most of the organs, the most usual being nephritis, the glomeruli of the kidney being especially affected, and hæmorrhages being also noticed in the straight tubes. Lesions in the cellular structure of the labyrinth were particularly common. These pathological changes contrast very strongly with those observed in acute poisoning by mercury in such cases there is a granular infiltration in the secreting cells of Heidenhain, this infiltration produces an exaggeration of the striation naturally seen in the cells of the convoluted tubes. On closer examination, again, minute traces of hæmoglobin were found in these cells. On examination of the deposit obtained from the urine similar particles of hæmoglobin were found. The histological appearances corresponded exactly with the symptoms observed during life—albuminuria and hæmoglobinuria.

CHLORIDE OF ZINC IN PULMONARY TUBERCULOSIS

Dr. Jules Comby publishes in *L'Union Médicale* No 1, 1893, the results of injections of chloride of zinc in cases of pulmonary tuberculosis. All the cases were early ones, the disease being confined to the apices. The strength of solution employed varied from 1 in 50 to 1 in 20. No bad local effects were produced nor were any unpleasant constitutional symptoms noted. Three drops were introduced by the means of a hypodermic syringe, and the dose was repeated every third or fourth day until four to six injections had been given. The results, Dr. Comby considered, were favourable in the three cases in which he tried the treatment and he maintains that it merits further trial. He was able to demonstrate that a solution of chloride of zinc in the strength above stated could be injected into the lungs, two or three drops at a time, without any danger and the injections might be repeated without further risk. His object is to produce a cure in the same manner as occurs in the natural arrest of the disease—namely by development of fibrous tissue. By his experiments on tubercular joints he claims that chloride of zinc tends to promote the formation of fibrous tissue and thus to bring about the desired result.

NAPHTHOL AS A VERMIFUGE.

Naphthol having recently been recommended as a vermifuge, M. Dubois of Amiens has reported a case in which he found it successful after all other vermifuges had failed. The patient was a girl of sixteen who had suffered from vomiting for several months and the diagnosis pointed to worms as the cause the vomiting continuing in spite of varied treatment and the girl becoming much emaciated, he decided to order four grains of naphthol three times a day. In the course of a few days she passed thirty-four round worms the vomiting then ceased and recovery was rapid.

BORATE OF SODA IN PARALYSIS AGITANS

Borate of soda, which has been found useful by various authorities in epilepsy has been tried with remarkable success by Dr. Sacaze, *chef de clinique* in Professor Grasset's wards in Montpellier in a case of paralysis agitans where the actual current electricity, suspension, iodides and various other forms of treatment had proved fruitless. The drug was given at first in four grain powders three times a day and after a few days the dose was gradually increased

to about double that quantity. An improvement was manifest by the end of the first week, and after that the patient's condition continued to improve still further. After a time he was able to walk, to speak distinctly to feed himself, and to write, none of which things he could accomplish before the borate of soda was commenced. No disagreeable effects were produced by the drug.

THE ACTION OF ANTIPIRETICS OF THE AROMATIC SERIES ON THE BLOOD

M. Schmidt Professor of Therapeutics at Nancy, has made a series of experiments as to the action of fourteen antipyretics on the blood. He experimented on guinea pigs, rabbits and dogs, some of which were in a healthy condition, whilst others were rendered febrile by the injection of septic or tuberculous matter. He found that all the aromatic antipyretics which he studied caused in a greater or less degree alterations in the blood—the fixation of oxygen by hæmoglobin, the transformation of oxyhæmoglobin into methæmoglobin, the diminution of the respiratory capacity of the blood and even destruction of the corpuscles. These alterations vary according to the nature and dose of the agent, but they all bear some relation to both the period and the extent of the antipyretic action. The substances may be divided into the three following groups: (1) those (such as phenacetin and antipyrin) which in a medium dose (that is to say a dose causing a thermic depression of 1°, 2° or 3° C) only produce the fixation of oxygen by hæmoglobin, (2) those, such as anisic acid thallin, eutibermine, kaurin, exalgin, methacetin and acetilamidophenol, which in a medium dose only produce intra-corporal methæmoglobinæmia, (3) those such as anilides (acetanilide or antifebrin, formanilide, methylformanilide) and pyrocin, which in medium doses (especially repeated ones) produce methæmoglobinæmia with destruction of corpuscles. Dr. Schmidt believes that these narcotics may be found to be excellent analgesics in the case of patients whose corpuscles are healthy, intact and resistant, but as antithermics their value is open to question and they are for the greater part dangerous on account of their toxic action on the blood. They should on no account be given to uræmic subjects who all have too little hæmoglobin and too few corpuscles, nor should they be given to patients suffering from fever, when the corpuscles have already been affected. Their action, however, on the corpuscles being of short duration, they may be employed in cases of hyperpyrexia in order to bring the temperature down to a less dangerous point, or they may be used in ephemeral fevers, for these phenacetin, or, better still, antipyrin, is useful as having the least effect on the blood. Antipyrin in small doses never gives rise to methæmoglobin.

BROMIDE OF ETHYL ANÆSTHESIA.

Dr. L. S. Ginsburg in his graduation dissertation in the Imperial Medical Academy of St. Petersburg gives an account of a large number of observations on the pharmacological action of bromide of ethyl on dogs and rabbits which he carried out in Professor Pavloff's laboratory. He administered it by inhalation, by artificial respiration of the vapour and by intravenous injection of an emulsion. He finds that the inhalation of air containing a small quantity of the vapour induces sleep, the blood pressure remaining normal and the pulse becoming more rapid though not losing its regularity. If the air is charged to a greater degree with the vapour the blood pressure is at first markedly lowered, but in consequence of the changes in the respiration and the consequent diminution of vapour inhaled the blood pressure afterwards rises to a little above normal. The irregularities of the cardiac pulsation which occur during the diminished blood pressure disappear as it rises again. If the air is charged with a very large quantity of the vapour there occurs only a slight secondary rise of the blood pressure, doubtless because of the injurious effect of the vapour upon the regulating centre of respiration. In this case respiration is rapidly arrested. The acceleration of the pulse after the inhalation of air containing a small quantity of vapour depends on the stimulation of the automatic cardiac centres or of the accelerator nerves. The slowing which follows the inhalation of a series of large doses is due to the diminution of the irritability of the cardiac muscle. The fall in the blood pressure arises from paralysis of the peripheral vaso-motor nerves, and if the doses are large the heart assists in producing this fall. Bromide of ethyl has no effect on the pneumogastric nerves the vaso-dilator centres or on the peripheral vaso-dilator nerves. Dr. Ginsburg's researches

destination and addresses at such places, their landing at our ports can and should be refused. In some ports action as to this has been suspended, in the Port of London it has not been felt safe to forego the requirements of the Order during the winter months, and at all ports it may soon become necessary to put the terms of the Order into operation again as regards the classes referred to. But such action has no reference to anything other than the protection of the public health from cholera. If alien immigration comes to be dealt with as a whole and for other purposes, it will not be on medical grounds such as those to which the terms of the Cholera Order are limited.

FOREIGN UNIVERSITY INTELLIGENCE

Chicago (College of Physicians and Surgeons)—Dr Henry T Byford has been appointed to the chair of Gynecology in succession to the late Dr Reeves Jackson.

Marseilles—Dr Magail, Professor of Clinical Midwifery, has retired and Dr A. E. Queirel has been appointed to succeed him.

Palermo—Dr Tansini of Modena, has been appointed Professor of Clinical Surgery.

Paris—Dr Brouardel, Professor of Forensic Medicine, has been appointed Dean of the Medical Faculty for a term of three years.

Philadelphia (Jefferson College)—Dr Schweinitz has been appointed Professor of Ophthalmology.

St Petersburg (Military Medical Academy)—Drs G. U. Yavein, S. S. Botkin and M. M. Volkoff have been recognised as *privat-docenten* in Clinical Medicine and Dr B. V. Tomashevski as *privat-docent* in Clinical Neurology.

Tomsk—Dr A. T. Sudakoff, Professor of Hygiene and Medical Statistics, has been appointed Rector of the University for a term of four years in succession to Dr Velik, Professor of Physiology.

Turin—Dr Dionisio has been recognised as *privat-docent* in Laryngology and Rhinology.

THE seventh session of the French Congress of Surgery will be held in Paris at the Faculté de Médecine on Monday, April 3rd, 1893, under the Presidency of Professor Lannelongue of Paris. The first meeting—devoted to various subjects—will take place at 9 A.M., in the grand amphitheatre of the École de Médecine. The chief inaugural meeting will take place at 2 P.M. Two subjects have been selected for consideration by the Congress—(1) Fibrous Tumours of the Uterus, (2) the Surgical Treatment of Tuberculous Diseases of the Foot. The mornings will be devoted to visiting the hospitals and to the discussion of diverse subjects. Members are requested to send the titles and abstracts of their papers, not later than Feb. 15th, to M. Félix Alcan, Secretary, 108, Boulevard St. Germain, to whom also all requests for information concerning the Congress may be addressed.

IN the paragraph in last week's issue announcing the appointment of Dr Anderson Stuart as Medical Adviser to the Government of Sydney, N.S.W., it was unfortunately stated, owing to a clerical error, that the appointment was made "in the place of Dr F. Norton Manning, 'deceased'." The latter word should have read "resigned." We sincerely trust that the mistake, which we much regret, has not caused either inconvenience to Dr Manning or anxiety to his numerous friends.
